Abstract

A series of new triindolylmethane-based compounds including those containing reactive functional groups were synthesized by the tandem addition–elimination–(Michael) addition reaction from 1H-indole and 1H-indole-3-carbaldehyde. The thermal, optical, photophysical and photoelectrical properties of the synthesized compounds were studied. The synthesized compounds exhibit moderate thermal stability with 5% weight loss temperatures ranging from 245 to 310 °C and form glasses with glass transition temperatures in the range of 98–123 °C. The ionization potentials of the synthesized compounds measured by the electron photoemission in air technique range from 5.67 to 5.80 eV. The solutions of the synthesized compounds show relatively high triplet energies in the range from 2.97 to 2.99 eV.

1. Introduction

Since the first demonstration of efficient light emission from organic light emitting diodes (OLEDs) by the Kodak group [1], the foci of further research were on lower operating voltages, higher efficiencies and longer lifetimes of the devices. Over the past several years, organic electroluminescent devices have attracted growing interest for full-color flat-panel display applications because of their ability to emit colors throughout the visible spectrum and with high luminous efficiency [2]. The efficiency of light emission from fluorescent OLEDs is limited compared to OLEDs with phosphorescent (triplet) emitters. In a device without triplet emitters only the singlet excitons can recombine radiatively. Consequently, such a device has a maximal internal efficiency of 25%. When triplet emitters are used in a device, the maximal internal efficiency can be as high as 100% since the triplet emitters can harvest both singlet and triplet excitons [3]. The way to improve the efficiency of OLEDs is the use of an appropriate choice of phosphorescent dye dopants diluted in a host material with wide energy gap. Efficient electrophosphorescence can be generated by energy transfer from the host to the phosphorescent guest molecule. A good host material should possess three intrinsic criteria: (1) its triplet energy must be higher than that of the guest molecule to prevent backward energy transfer during operation [2,4,5]; (2) the conjugation in the host molecules must be extremely confined; (3) it must possess good morphological and chemical stabilities to extend the operational lifetime of the device.

Although 4,4′-bis(9-carbazolyl)-2,2′-biphenyl (CBP) has been commonly used as a host material in green and red phosphorescent devices, the triplet energy of CBP (2.56 eV) is lower than those of the general blue triplet emitters (>2.62 eV), resulting in an inefficient energy transfer from host to guest. Thus one of the major research efforts in phosphorescent OLEDs has been due to the development of host materials with large triplet energies with thermal stability. Currently, effective host materials reported for phosphorescent devices are limited within few
structural features such as carbazole [6–8], dibenzofuran [9], phenylsilane [10] and fluorene [11] derivatives. In this paper we report on the synthesis and properties of new potential high triplet energy materials. We have chosen tri(1H-indol-3-yl)methane moiety as a major building block for the design and synthesis of the potential high triplet energy materials. In this moiety three indolyl fragments are connected at the C-3 position to the sp³ hybridized carbon atom which serves as a spacer to block π-conjugation. Some compounds reported in this article contain reactive oxiranyl and oxetanyl reactive functional groups. Such compounds could be of interest for the application of multilayer devices with (photo)cross-linked layers.

2. Experimental

2.1. Materials

The starting compounds, i.e. 1H-indole, 1H-indole-3-carboxaldehyde, iodoethane, 1-iodobuthane, 2-(chloromethyl)xorirane, and 1-ethyl-4-iodobenzene were purchased from “Aldrich” and used as received. 3-(Bromomethyl)-3-methylxethane (Chemada, Israel) was also used as received. All the required chemicals, i.e. potassium hydroxide, sodium sulphate, tetra-butylammonium hydroxide sulphate (TBAS), copper(I) iodide, trans-1,2-diaminocyclohexane, and concentrated hydrochloric acid were purchased from “Aldrich” and “Fluka”. Organic solvents such as acetone, butan-2-one, toluene, 1,4-dioxane, and 0.01 g (0.03 mmol) of TBAS were heated at reflux in 200 ml methanol and then cooled to room temperature. The pale yellow solid was collected by filtration and washed with several portions of methanol to afford the product as a mixture which was purified by column chromatography using hexane/chloroform (9:1, v/v). The pale yellow solid was collected and dried by standard methods [12].

Tri(1H-indol-3-yl)methane (1): a mixture of 7.25 g (0.05 mol) 1H-indole, 11.71 g (0.1 mol) 1H-indole-3-carboxaldehyde, 1 ml concentrated hydrochloric acid and 200 ml methanol was heated at reflux for 3 h and then cooled to room temperature. The pale yellow solid was collected by filtration and washed with several portions of methanol and then recrystallized from toluene to afford the product as a major building block for the design and synthesis of the potential high triplet energy materials. In this moiety three indolyl fragments are connected at the C-3 position to the sp³ hybridized carbon atom which serves as a spacer to block π-conjugation. Some compounds reported in this article contain reactive oxiranyl and oxetanyl reactive functional groups. Such compounds could be of interest for the application of multilayer devices with (photo)cross-linked layers.

  Tri(1-(4-ethylphenyl)-1H-indol-3-yl)methane (6). Tri(1H-indol-3-yl)methane (I) (3 g) (8.30 mmol), 1-ethyl-4-iodobenzene 6.16 g (26.54 mmol), copper(I) iodide 0.04 g (0.21 mmol), of dry 1,4-dioxane under N₂ atmosphere. The reaction mixture was cooled down to ambient temperature. The inorganic components were removed by filtration. The solvents were removed by distillation under reduced pressure. The crude product was purified by silica gel column chromatography using hexane/chloroform (5:1, v/v) as an eluent. The product was purified by silica gel column chromatography using hexane/chloroform (5:1, v/v) as an eluent. The product was identified by IR absorption, ¹H NMR and mass spectrometries and was confirmed by the characteristic aromatic absorption at 3048–3050 cm⁻¹ (C–H stretch), aliphatic absorption at 2962–2972 cm⁻¹ (C–H stretches (compounds 2–6)), at 1455–1466 cm⁻¹ (C=C stretches) and absorption at 1333–1361 cm⁻¹ due to C–N stretching are clearly observed in the IR spectra of all tri(1H-indol-3-yl)methane-based compounds. The characteristic C–O–C bands at 1225 and 1192 cm⁻¹ are observed in the IR spectra of 4 and 5, respectively.

3. Results and discussion

Tri(1H-indol-3-yl)methane (I) was synthesized by the tandem addition–elimination–(Michael) addition reaction from 1H-indole and 1H-indole-3-carbaldehyde in the presence of concentrated hydrochloric acid [13]. Compounds 2–5 were obtained as described in Scheme 1 by alkylation of 1 with iodoethane, 1-iodobutane, 2-(chloromethyl)oxirane and 3-(bromomethyl)-3-methylbutane, respectively in the presence of a phase transfer catalyst (TBAS) and potassium hydroxide. Compound 6 was synthesized by Ullmann–Goldberg coupling of 1-ethyl-4-iodobenzene with tri(1H-indol-3-yl)methane 1 in the presence of copper(I) iodide, potassium carbonate and trans-1,2-cyclohexane as a ligand [15]. All these compounds were identified by IR absorption. ¹H NMR and mass spectrometries and elemental analysis. They are soluble in common organic solvents such as chloroform, dichloromethane, toluene and tetrahydrofuran.

The characteristic aromatic absorption at 3048–3050 cm⁻¹ (C–H stretch), aliphatic absorption at 2962–2972 cm⁻¹ (C–H stretches (compounds 2–6)), at 1455–1466 cm⁻¹ (C=C stretches) and absorption at 1333–1361 cm⁻¹ due to C–N stretching are clearly observed in the IR spectra of all tri(1H-indol-3-yl)methane-based compounds. The characteristic C–O–C bands at 1225 and 1192 cm⁻¹ are observed in the IR spectra of 4 and 5, respectively.
Scheme 1. (a) C₂H₅I, KOH, [Bu₄N]HSO₄, acetone, T=60 °C; (b) C₄H₉I, KOH, [Bu₄N]HSO₄, acetone, T=60 °C; (c) 2-(chloromethyl)oxirane, KOH, Na₂SO₄, T=25 °C; (d) 3-(bromomethyl)-3-methyloxetane, KOH, [Bu₄N]HSO₄, butan-2-one, T=25 °C; (e) 1-ethyl-4-iodobenzene, CuI, \textit{trans}-1,2-diaminocyclohexane, K₂CO₃, toluene, 1,4-dioxane, 115 °C.

The signals in \(^1\)H NMR spectra of the synthesized compounds can be assigned to the characteristic aromatic and aliphatic hydrogen atoms. The proton signals at 6.09–6.36 ppm can be assigned to the protons of central CH group of compounds 1–6.

The thermal properties of the synthesized hosts were examined by DSC and TGA under a nitrogen atmosphere. The values of glass transition temperatures, crystallization temperatures (T\(_{\text{cr}}\)), melting points (T\(_{\text{m}}\)) and 5% weight loss temperatures (T\(_{\text{ID}}\)) are summarized in Table 1. Alkyl substituted derivatives 2 and 3 exhibit lower thermal stability than oxiranyl, oxetanyl and aryl substituted derivatives 4–6. Arylated derivative of tri(1H-indol-3-yl)methane 6 demonstrates the highest thermal stability among the synthesized triindolylmethane-based compounds.

Compounds 2–6 were obtained as crystalline materials, however all of them except compound 6 could be transformed into the glassy state with the relatively high glass transition temperatures ranging from 75 to 123 °C. Fig. 1 shows DSC curves of compound 5. Compound 5 obtained as a crystalline material in the first DSC heating scan showed only endothermic melting signal at 243 °C. After the slow recooling the second heating scan revealed glass transition at 98 °C, exothermic crystallization signal at 175 °C and again melting signal. Thus it can be regarded as molecular glass. All the synthesized compounds show crystallization signals in the second heating scan. This observation can be explained by the regular structure of triindolymethanes, influenced by sp\(^3\) hybridized carbon (CH group). The glass transitions were recorded for all the materials except 6.

The synthesized compounds were studied by UV–vis and luminescence spectrometries. The absorption spectra of compounds 2–5 are similar due to the presence of the same chromophore. They exhibit absorption band in the range of 243–325 nm due to \(\pi \rightarrow \pi^*\) electronic transitions. The spectrum

of compound 6 has additional high-energy absorption band due to the presence of 4-ethylphenyl group. The data pertinent to the absorption maxima of triindolymethane-based compounds are given in Table 2. For the comparison, the corresponding data for 1-(oxiran-2-ylmethyl)-1H-indole (EPI) [16] are presented. The UV absorption bands of all the synthesized triindolymethane-based compounds show bathochromic shift with respect to the absorption band of EPI and the enhanced values of molar extinction coefficient ($\varepsilon_{\text{max}}$). The spectrum of compound 6 shows the highest values of $\varepsilon_{\text{max}}$ and the most considerable bathochromic shift with respect to the spectrum of EPI. This is apparently the consequence of the enlarged conjugated $\pi$-electron system of compound 6.

Fig. 2 shows the fluorescence and phosphorescence emission spectra of dilute toluene solutions of the selected compounds recorded at 77 K using the excitation wavelength $\lambda_{\text{ex}}$ of 300 nm. The pertinent data are summarized in Table 3. The fluorescence spectra of compounds 2, 4 and 6 are very similar. No red shift of the spectrum of compound 6, which was characteristic of the UV spectrum, is observed. The phosphorescence spectra of compounds 2, 4 and 6 are also similar. The triplet energies $E_T$ established from the highest energy phosphorescence peaks of the dilute solutions of these compounds are almost identical, i.e. 2.97–2.99 eV (Table 3). These values of triplet energies are higher than those reported for the common triplet blue emitters used in electrophosphorescent devices iridium(III) bis[(4,6-difluorophenyl)pyridinato-N,C2’] (FIrpic) 2.62 eV and [(dpppy)2Ir(fppy)] (FIrdpfpy) 2.68 eV [11].

Fig. 3 shows fluorescence and phosphorescence spectra of the spin-coated thin-film samples of compounds 2, 4 and 6. The data pertinent to the intensity maxima of these spectra are given in Table 3. Fluorescence spectra of the films are similar to those of dilute solutions. However phosphorescence intensity maxima of the films of 2, 4 and 6 exhibit considerable bathochromic shifts with respect to the corresponding max-

ima of the spectra of dilute solutions, as typically observed for various phosphorescent host materials [6]. For the highest energy phosphorescence peaks, which are used for the estimation of triplet energies, these shifts are from 23 nm for 2 and 6 to 33 nm for 4. For the highest intensity phosphorescence peaks the bathochromic shifts are from 26 nm for 6 to 67 nm and 68 nm for 2 and 4, respectively. Thus in the films triplet emission occurs at lower energy. Apparently intermolecular interaction, e.g. formation of triplet excimers takes place in the solid samples of the synthesized triindolylmethane-based compounds. The smallest bathochromic shift was observed for the phosphorescence spectra of the solid sample of 6. The presence of 4-ethylphenyl groups in these molecules apparently hinders the formation of excited dimers. The triplet energies established from the highest energy phosphorescence peaks of these compounds in the solid state are slightly lower than in dilute solutions (Table 3).

An important characteristic of electronically active compounds is ionization potential, which characterizes the electron releasing work under illumination. $I_p$ values for the thin films of the synthesized compounds were established by electron photoemission technique from the dependencies of photocurrent ($I_p$) on the incident light quanta energy, which are named as electron photoemission spectra and plotted as $\phi^{0.5} = f(\hbar \nu)$. Fig. 4 shows electron photoemission spectra of the films of compounds 2–6. Electron photoemission spectrum of EPI is given for the comparison. The intersection points of the straight lines down with abscissa axis give the values of the ionization potentials. The values of $I_p$ in eV are 5.72 for 2, 5.78 for 3, 5.80 for 4, 5.74 for 5 and 5.67 for 6 and 5.80 eV for EPI. It is evident that replacing alkyl groups by aryl group shifts the ionization potential to lower energy. These data are consistent with UV and fluorescence data. Generally, the ionization potentials of the synthesized compounds are close to those of the derivatives of carbazole, 3,3′-bi(9H-carbazole) and fluorene used as host materials in the emission layers of electrophosphorescent devices [9].

In conclusion, we have synthesized a series of new triindolylmethane-containing compounds and have studied their thermal, optical, photophysical and photoelectrical properties. The synthesized compounds exhibit moderate thermal stability with 5% weight loss temperatures ranging from 245 to 310 °C and form glasses with glass transition temperatures in the range of 98–123 °C. The ionization potentials of the synthesized materials measured by the electron photoemission in air technique range from 5.67 to 5.80 eV. The synthesized compounds show relatively high triplet energies in the range from 2.97 to 2.99 eV.
