ABSTRACT: A novel interpretation of transducer power gain (GT) is presented by optical analogy. By employing scattering parameters of the input/output matching network and the transistor, we have developed a simple method to derive GT. In addition to simplicity, our theory also has the advantage of giving the physical meaning for each term of the formula of GT. © 2001 John Wiley & Sons, Inc. Microwave Opt Technol Lett 31: 124–126, 2001.

Key words: transducer power gain; scattering parameters; transistor

INTRODUCTION

It is well known that the transducer power gain (GT) is one of the most important figures of merit in the design of microwave transistor amplifiers. Several methods [1–4] have been proposed to derive the transducer power gain. However, most of them rely heavily on mathematical calculations rather than simple physical reasoning, and therefore it is difficult to give a physical meaning to each term in the formula of GT. In view of this, we have developed a simple and intuitive way to derive GT by means of optical analogy. In the derivation, the concept of incident and reflected waves is employed to simplify the circuit analysis, and the physical insight into each term in GT is naturally obtained. Our theory also provides a useful transformation between the different methodologies of optics and microwave circuit design.

THEORY

The block diagram of a microwave transistor amplifier is shown in Figure 1(a), where VS is the voltage source, ZO is 50 Ω, and Gs and Gt are the source and load reflection coefficients in a ZO system. PWS and PL represent the available power of the signal source and the power delivered to the load ZO, respectively. The input and output matching networks are assumed to be passive and lossless.

In order to obtain the transducer power gain, i.e., PPL/PWS, by optical analogy, we first replace components in the microwave circuit by optical components. The resultant optical system is shown in Figure 1(b), where the signal source in the amplifier has been replaced by a light source with power of PWS, the input matching network by a lossless partially transmitting mirror with a reflection coefficient of Gs (at plane 2) looking toward the source, the output matching network by a lossless partially transmitting mirror with a reflection coefficient of Gt (at plane 5) looking toward the load, and finally, the transistor by an optical gain medium. Note thatZO, because of their nonreflecting property in a ZO system, were replaced by empty space in this optical system. Also note that Gs, in fact, is the S22 of the input mirror and Gt is the S11 of the output mirror. Because any linear network that contains no controlled sources will be reciprocal [5], the S-matrix of the input/output matching network will be symmetric [6]. Further, owing to the lossless property of the input/output matching network, the S-matrix is also unitary [6]. It is proven that the magnitudes of S11 and S22 of a symmetric network will be equal [7], and hence the magnitude of the reflection coefficient Gs (i.e., S11) of the input mirror at plane 1 looking toward the load is equal to that of Gt, namely,

\[ |G_s| = |G_t|. \]  (1)

Equation (1) is the key point of our proposed theory. The S-matrix of the input mirror can be easily derived from (1) due to its lossless and unitary properties [6, 7] as follows:

\[ [S]_{\text{input}} = \begin{bmatrix} \Gamma_s' e^{i\phi_1} & \sqrt{1 - |\Gamma_s|^2} e^{i\phi_1} \\ \sqrt{1 - |\Gamma_s|^2} e^{i\phi_2} & \Gamma_s \end{bmatrix} \]  (2)

where \( \phi_1 \) is an arbitrary phase angle. Similarly, the S-matrix of the output mirror can be written as

\[ [S]_{\text{output}} = \begin{bmatrix} \Gamma_L & \sqrt{1 - |\Gamma_L|^2} e^{i\phi_2} \\ \sqrt{1 - |\Gamma_L|^2} e^{i\phi_1} & \Gamma_L' \end{bmatrix} \]  (3)

where \( \phi_2 \) is another arbitrary phase angle.

When the light source with power \( P_{WS} \) is incident from the left on the input mirror as shown in Figure 1(b), it is partially reflected and partially transmitted. According to basic electromagnetic theory [8], the transmitted power is

\[ |a_1|^2 = P_{WS} \times (1 - |G_s|^2) = P_{WS} \times (1 - |G_t|^2) \]  (4)

where \( a_1 \) is the normalized amplitude of the transmitted light. However, this transmitted light continues to the optical gain medium. Here, the portion \( S_{11} \cdot a_1 \) is reflected, and the portion \( S_{21} \cdot a_1 \) is transmitted. The reflected part is returned to the input mirror and then reflected: \( \Gamma_s' \cdot S_{21} \cdot a_1 \). This amplitude, reflected from the input mirror, goes through the same process as the initially transmitted light \( a_1 \). Each repetition of the process amounts to multiplication by \( \Gamma_s' \cdot S_{11} \). Therefore, the total wave leaving the input mirror and incident on the gain medium (see Fig. 2) is

\[ a = a_1 \left( 1 + \Gamma_s' \cdot S_{11} + (\Gamma_s' \cdot S_{11})^2 + \cdots \right) = \frac{a_1}{1 - \Gamma_s' \cdot S_{11}} \]  (5)

where \( a \) is the normalized amplitude of the total wave. Since the power of a wave is the square of its amplitude, the actual
power incident into the gain medium is

\[ |a|^2 = \frac{|a_j|^2}{|1 - \Gamma_S \cdot S_{11}|^2} = P_{AVS} \frac{1 - |\Gamma_3|^2}{|1 - \Gamma_S \cdot S_{11}|^2}. \]  

(6)

From the definition of \( S_{21} \), the power coming out of the gain medium can be easily written as

\[ |a_2|^2 = |a \cdot S_{21}|^2 = P_{AVS} \frac{1 - |\Gamma_3|^2}{|1 - \Gamma_S \cdot S_{11}|^2} |S_{21}|^2 \]  

(7)

where \( a_2 \) is the normalized amplitude of the light just coming out of the gain medium. When \( a_2 \) arrives at the output mirror, a portion \( \Gamma_L \cdot a_2 \) is reflected. The reflected part is returned to the gain medium, where a portion \( S_{22} \cdot \Gamma_L \cdot a_2 \) is reflected and a portion \( S_{22} \cdot \Gamma_L \cdot a_2 \) is transmitted. The transmitted part continues to the input mirror, and is reflected: \( \Gamma_S \cdot S_{12} \cdot \Gamma_L \cdot a_2 \). This reflected wave experiences multiple reflections between the input mirror and the gain medium, and finally, a total wave incident on the gain medium is \( \Gamma_S \cdot S_{12} \cdot \Gamma_L \cdot a_2/(1 - \Gamma_S \cdot S_{11}) \), which is then transmitted through the

\[ P_{AVS} = \frac{1 - |\Gamma_3|^2}{|1 - \Gamma_S \cdot S_{11}|^2} \]  

Figure 1 (a) Block diagram of a microwave amplifier. (b) Optical analogy of the microwave amplifier circuit in (a).

gain medium with an amplitude of $S_{22} \cdot \Gamma_L \cdot a_2 + \frac{S_{21} \cdot \Gamma_S \cdot S_{12} \cdot \Gamma_L \cdot a_2}{1 - \Gamma_S \cdot S_{11}}$. This amplitude has to be added to the initial reflected wave $S_{22} \cdot \Gamma_L \cdot a_2$, and their sum becomes

$$S_{22} \cdot \Gamma_L \cdot a_2 + \frac{S_{21} \cdot \Gamma_S \cdot S_{12} \cdot \Gamma_L \cdot a_2}{1 - \Gamma_S \cdot S_{11}} = \left( S_{22} + \frac{S_{21} \cdot \Gamma_S \cdot S_{12} \cdot \Gamma_L \cdot a_2}{1 - \Gamma_S \cdot S_{11}} \right) \cdot \Gamma_L \cdot a_2$$

$$= \Gamma_{out} \cdot \Gamma_L \cdot a_2$$  \hspace{1cm} (8)

where $\Gamma_{out}$ is defined as $S_{22} + S_{21} \cdot \Gamma_S \cdot S_{12}/(1 - \Gamma_S \cdot S_{11})$. This summed reflected wave in (8) goes through the same process as the initially transmitted light $a_2$. Clearly, each repetition of the process amounts to multiplication by $\Gamma_{out} \cdot \Gamma_L$. Therefore, the total wave leaving the gain medium and incident on the output mirror (see Fig. 3) is

$$a_3 = a_2 \left(1 + \Gamma_{out} \cdot \Gamma_L + (\Gamma_{out} \cdot \Gamma_L)^2 + \cdots \right) = \frac{a_2}{1 - \Gamma_{out} \cdot \Gamma_L}$$  \hspace{1cm} (9)

and its associated power is

$$|a_3|^2 = \left| \frac{a_2}{1 - \Gamma_{out} \cdot \Gamma_L} \right|^2 = P_{AV} \cdot \frac{1 - |\Gamma_L|^2}{|1 - \Gamma_S \cdot S_{11}|^2} |S_{21}|^2 \cdot \frac{1}{|1 - \Gamma_{out} \cdot \Gamma_L|^2}$$  \hspace{1cm} (10)

where $a_3$ is the normalized amplitude of the total wave incident on the output mirror. Since the reflection coefficient of the output mirror is $\Gamma_L$, it is clear that the power $P_L$ coming out from the output mirror is

$$P_L = |a_3|^2 \left(1 - |\Gamma_L|^2 \right)$$

$$= P_{AV} \cdot \frac{1 - |\Gamma_L|^2}{|1 - \Gamma_S \cdot S_{11}|^2} |S_{21}|^2 \cdot \frac{1 - |\Gamma_L|^2}{|1 - \Gamma_{out} \cdot \Gamma_L|^2}$$  \hspace{1cm} (11)

$P_L$ corresponds to the power delivered to the load in the microwave amplifier, and hence from the above equation (11), the transducer power $G_T = P_L / P_{AV} \cdot S$ can be found to be

$$G_T = \frac{1 - |\Gamma_{out}|^2}{|1 - S_{12}\Gamma_{out}|^2} \frac{1 - |\Gamma_L|^2}{|1 - \Gamma_{out}\Gamma_L|^2}.$$  \hspace{1cm} (12)

CONCLUSION

A novel interpretation of the formula of transducer power was presented. The derivation was based on the scattering parameters of the input/output matching network and the transistor and optical system associated with them. It was found that $1 - |\Gamma_L|^2$ represents the fraction that the signal power transmits through the input matching network, and $1/|1 - \Gamma_S \cdot S_{11}|$ accounts for the multiple reflections of the transmitted wave between the input matching network and the transistor. $|S_{21}|^2$ is the power gain of the transistor. $1/|1 - \Gamma_L \cdot \Gamma_{out}|$ takes into account the multiple reflections between the transistor and the output matching network, as well as those between the input matching network and the transistor.
