Abstract

The complexes \([Cu_2(dppa)_3(CH_3CN)_2][BF_4]_2\) (1) and \(Cu_2(dppa)_3(O_3SCF_3)_2\) (2) have been prepared in good yields by treating \([Cu(MeCN)_4][BF_4]\) and \([Cu(MeCN)_4][O_3SCF_3]\), respectively, with \(Ph_2PC≡CPPh_2\) (abbreviated as dppa) at room temperature. The reaction of 1 with di-2-pyridyl ketone (abbreviated as dpyk) produces \([Cu_2(dppa)_2(dpyk)_2][BF_4]_2\) (3), and with 1,1′-bis(diphenylphosphino)ferrocene (abbreviated as dppf) produces \([Cu_2(dppa)(dppf)_2][BF_4]_2\) (4). The molecular structures of 1–4 have been determined by an X-ray diffraction study. Compounds 1 and 2 form a helical \(Cu_2(dppa)_3\) metallatricycle, compounds 3 forms a \(Cu_2(dppa)_2\) metallacycle, and compound 4 contains a linear \(Cu_2(dppa)\) skeleton.

Keywords: Dicopper(I) complexes; Bis(diphenylphosphino)acetylene; 1,1′-Bis(diphenylphosphino)ferrocene

1. Introduction

The ‘coordination clusters’ assembling from monometallic complexes and multidentate bridging ligands have received much attention due to their potential applications in catalysis, molecular recognition and photoactive device [1–6]. Recently, interest in the design and synthesis of discrete copper cluster complexes was stimulated by the structural elucidation of several dis-, tri- and tetra-nuclear copper centers in biologically active molecules [7–9]. Bis(diphenylphosphino)acetylene (abbreviated as dppa) is a potentially trifunctional ligand, where the two phosphorus centers are normally coordinated to metals in advance of the acetylene group due to stronger net donor capability of the phosphine ligand compared with alkyne [10]. However, the rigidity of the linear —C≡C— backbone constrains the dppa ligand to bridge between metal centers, forming either dimeric or polymeric coordination compounds [11–15]. We previously reported the preparation and reactivity of a tris(dppa) ditungsten complex [16]. In this paper, we present the syntheses and characterization of four new dinuclear Cu(I) complexes bridged by three, two and one dppa ligands.

2. Results and discussion

The reaction of \([Cu(MeCN)_4][BF_4]\) and dppa ligand in a 2:3 ratio has been carried out at room temperature to afford \([Cu_2(dppa)_3(CH_3CN)_2][BF_4]_2\) (1) in 93% yield after crystallization. In contrast, the analogous reaction of \([Cu(MeCN)_4][O_3SCF_3]\) with dppa produces \(Cu_2(dppa)_3(O_3SCF_3)_2\) (2) in 98% yield, of which the trifluorosulfonate counter anion is bonded to each copper(I) center through the oxygen atom. Compounds 1 and 2 consist of two copper(I) atoms bridged by three dppa ligands, while the
former contains two labile acetonitrile species susceptible to further ligand substitution. It is of interest to investigate the reactivity of 1 towards bidentate ligands to see whether the M₂L₃ cage framework is affected. Thus, compound 1 is treated with di-2-pyridyl ketone (abbreviated as dpyk) at room temperature to produce \([\text{Cu}_2(\text{dppa})_2(\text{dpyk})_2][\text{BF}_4]_2\) (3) in 97% yield, concomitant with elimination of one dppa bridge. On the other hand, the reaction of 1 with the diphosphine ligand 1,1'-bis(diphenylphosphino)ferrocene (abbreviated as dppf) results in \([\text{Cu}_2(\text{dppa})(\text{dppf})_2][\text{BF}_4]_2\) (4) in 85% yield, which contains only one dppa bridge between the two \([\text{Cu}(\text{dppf})]\)⁺ moieties. The reactions are summarized in Scheme 1. Elimination of dppa bridges to give 3 and 4 may be attributed to chelating effects by the dpyk and dppf ligands. Previously, the importance of steric constraints in \([\text{Cu}(\text{PR}_3)_3]\)⁺ complexes was well established [17,18]. So it is likely for the copper atoms in 4 to adopt a trigonal configuration for steric reasons. In contrast, the planar dpyk ligand is less space-congested that the tetrahedral coordination retained for 3.

Compounds 1 and 2 form air-stable, colorless crystals. The FAB mass spectrum of 1 shows the molecular cation peak at \(m/z\) 654 (\(z = 2\)) for \(^{63}\text{Cu}\), and the ESI mass spectrum of 2 displays the ion peak at \(m/z\) 1457 corresponding to the \(\text{M}^+ - \text{O}_3\text{SCF}_3\) fragment. The \(^1\text{H}\) NMR of 1 presents a multiplet in the range \(\delta\) 7.43–7.11 for the phenyl protons and a singlet at \(\delta\) 2.61 for the methyl protons, while only a multiplet in the range \(\delta\) 7.55–7.08 is recorded for 2. The \(^{31}\text{P}\{^1\text{H}\}\) NMR spectra of 1 and 2 are comparable, showing a broad signal at \(\delta\) −26.70 and −28.21, respectively. The spectral data are in agreement with a \(D_3\) symmetry for 1 and 2 in solution.

The structure of 1 contains discrete cations \([\text{Cu}_2(\text{dp-}
\text{pa})_3(\text{CH}_3\text{CN})_2]^2+\), tetrafluoroborate counter anions and solvent molecules. The ORTEP drawing for the cation is depicted in Fig. 1, which consists of two \((\text{MeNC})\text{Cu}^+\) groups bridged by three dppa ligands. The coordination about the Cu⁺ ion can be described as a distorted tetrahedral, such that the P–Cu–P angles range from 103.01(4)° to 116.85(4)° and the N–Cu–P angles range from 108.8(1)° to 118.22(1)°.
The Cu–P–C (acetylene) angles show a slight deviation from the ideal tetrahedral with angles ranging from 108.2(1°) to 114.4(1°). The P–C–P backbones are slightly bowed as indicated by the P–C–P angles (average 175.2°), consistent with steric strains arising from the M2L3-type cage arrangement. The complex can be treated like three-bladed propellers, shown in Fig. 2, by looking down the Cu1–Cu2 axis. There is a helical twist of ca. 18.6° by taking the average of the torsional angles: P1–Cu1–Cu2–P2 18.2°, P3–Cu1–Cu2–P4 16.9° and P5–Cu1–Cu2–P6 20.8°. The related helical tris(dppa) complexes are Ni2(CO)2(dppa)3 [19], Mo2(CO)6(dppa)3 [14], W2(CO)6(dppa)3 [16], Cu2(X)2(dppa)3 (X = TeBu, SSiMe3) [20, 21], [Ag2(dppa)3]+ [22] and Au2(dppa)3Cl2 [23].

The molecular structure of 2, depicted in Fig. 3, is closely resemblant to 1, except that a trifluorosulfonate group is coordinated to each copper center through the oxygen atom. The P–Cu–P angles range from 106.17(2°) to 113.51(2°) and the O1–Cu1–P angles range from 101.30(5°) to 115.68(5°). The Cu1–O1–S1 angle of 132.1(1°) is substantially larger than the idealized bond angle of 109.5°, likely due to repulsions between the phenyl and CF3 groups. The helical twist for the Cu2(dppa)3 skeleton is 16.4° by taking the average of the torsional angles: P1–Cu1–Cu1A–P2 13.6°, P2A–Cu1–Cu1A–P1A 13.6° and P3–Cu1–Cu1A–P3A 22.0°. The P–C–C–P backbones are slightly bowed by the angles P1–C1–C2 178.8(2°), P2–C2–C1 175.6(2°) and P3–C3–C3A 174.2(2°).

The ORTEP drawing for the cation of 3 is depicted in Fig. 4. There is a crystallographic center of symmetry imposed on the molecule. Each Cu(I) atom is chelated by a dpyk ligand, and the two Cu(dpyk) groups are bridged by two dppa ligands. The Cu+ ion adopts a distorted tetrahedral coordination, with the bond angles ranging from 93.52(9°) for the N1–Cu–N2 bite to 122.21(6°) for the P1–Cu–N2 link. The Cu(dpyk) unit is envelope-like, where the N2, C7, C6, O1 and C5 atoms are planar to within 0.01 Å and the N1 and Cu atoms are 0.21 and 0.76 Å above the plane. The dihedral angle between the two pyridyl planes is 14.8°. The arrangement for the Cu3(dppa)2 moiety can be considered as a 10-membered chair-like dimetallacycle. The P1, P2, C12 and C25 atoms are coplanar to within 0.01 Å and the Cu atoms are 1.05 Å away from the plane. The P1–Cu–P2 plane makes a dihedral angle of 60.2° and 85.5° with the P1–P2–C12–C25 plane and the N1–Cu–N2 plane, respectively. The C5–C6–C7 angle is 126.4(2°) and the P–C–C angles are bowed by 6° in average from the idealized 180°.

Compound 3 forms an air-stable, bright yellow crystalline solid. The FAB mass spectrum displays the molecular cation peak at m/z 641 (z = 2). Interestingly, even though...
the two pyridyl groups are inequivalent (endo and exo), only one set of proton resonances are recorded down to \(-80\,^\circ\text{C}\). The \(^1\text{H}\) NMR spectrum at \(-60\,^\circ\text{C}\) is shown in Fig. 5, where the pyridyl protons are assigned on the basis of coupling pattern, and the triplet at \(\delta 7.48\) and the multiplet at \(\delta 7.25–7.14\) are attributed to the phenyl protons. Coincidence of the two pyridyl resonances is likely a result of accidental overlap, or a dynamic equilibrium involving fast flipping of the chair-like skeleton [24]. The \(^{13}\text{C}\{^1\text{H}\}\) spectrum is displayed in Fig. 6. The quaternary carbon signals at \(\delta 172.9\) (for C-O), 142.2 (for C-CO), 117.7 (a doublet with \(J_{P-C} = 42\,\text{Hz}\) for \(C_{(PPh)}^3\)-P) and 91.4 (for C-C) are assigned by comparing to the DEPT-edited spectrum shown above. The signals at \(\delta 139.1, 129.8, 118.4\) and 117.7 in about equal intensity can be assigned to the pyridyl carbons, and the remaining signals are attributed to the phenyl carbons.

Compound 4 forms air-stable, orange crystals. The FAB and ESI mass spectra display the highest ion peak at \(m/z\) 1011, corresponding to the species \([\text{Cu(dppa)}(\text{dppf})]^+\) or \([\text{Cu}_2(\text{dppa})_2(\text{dppf})_2]^{2+}\). However, a stoichiometry with the Cu:dppa:dppf ratio of 2:1:2 is suggested by the elemental
analysis and $^1$H NMR spectrum, which shows a 60H multiplet in the range $\delta$ 7.45–7.26 for the phenyl protons, and two 8H doublets ($J_{H-H} = 8$ Hz) at $\delta$ 4.37 and 4.14 for the Cp protons. The variable-temperature $^{31}$P{$^1$H} NMR spectra are presented in Fig. 7. At 25 °C, the two broad signals at $\delta$ −10.4 and −31.0 are assigned to the dppf and dppa ligands, respectively. At lower temperatures, they collapse and emerge as two sets of resonances at $\delta$ −7.78 and −13.29 for dppf and at $\delta$ −25.15 and −33.03 for dppa.
ligands. These data suggest a dynamic equilibrium between two conformers in solution. Because of the absence of diagnostic spectral features to reveal the structure of 4, a single-crystal X-ray diffraction study was performed.

The crystal of 4 contains discrete cations \([\text{Cu}(\text{dppa})(\text{dppf})_2]^{2+}\) and tetrafluoroborate counter anions. The ORTEP drawing for the cation is illustrated in Fig. 8. There is a crystallographic center of symmetry imposed on the molecule. Each Cu atom is chelated by a dppf ligand, and the two Cu(dppf) groups are bridged by one dppa ligand. The Cu atom is nominally three-coordinate. With the P1, P2 and P3 atoms forming the basal trigonal plane, the interligand bond angles surrounding the Cu atom are within 8° of the trigonal expectation of 120°; the three angles sum to 360°, consistent with the small displacement of the Cu atom from the basal trigonal plane (0.02 Å). The Cu, P1, P1A and CuA atoms are planar, which makes a dihedral angle of 33.0° with the P2–Cu–P3 plane. The two Cp rings are about parallel, with a dihedral angle of 1.5°, and the C1–P2 and C6–P3 vectors are staggered by 38.2°. The P2–Cu–P3 bite angle of 112.14(4)° is comparable with that of 109.31(2)° in \([\text{Cu}(\text{dppf})_3(\text{PPh}_2\text{C}_6\text{H}_4\text{CHO})]^+\) [18]. On the basis of the solid structure, the major isomer of 4 in solution (Fig. 7) may have the two Cu(dppf)\(^+\) groups in an anti position, and the minor isomer has the two Cu(dppf)\(^+\) groups in a gauche position, by projection down the P1–P1A axis.

In conclusion, we have prepared several dinuclear copper(I) complexes with one to three dppa bridges. Compounds 1 and 2 contain a helical Cu\(_2\)(dppa)\(_3\) structure, compound 3 forms a Cu\(_2\)(dppa)\(_2\) metallacycle, and compound 4 has a linear Cu\(_2\)(dppa) skeleton. The Cu⋯Cu distance is 6.25 Å for 1, 6.19 Å for 2, 6.29 Å for 3 and 7.78 Å for 4. It is promising that, by reacting with non-chelating agents such as 4,4′-bipyridine, the oligomer or polymer of 1 might be assembled. The investigation is progressive in our laboratory.

3. Experimental

3.1. General methods

All manipulations were carried out under an atmosphere of purified dinitrogen with standard Schlenk techniques. \([\text{Cu}(\text{MeCN})_4][\text{BF}_4]\) [25], \([\text{Cu}(\text{MeCN})_4][\text{O}_3\text{SCF}_3]\) [25], Ph\(_2\)PC≡CPPh\(_2\) [26] and 1,1′-bis(diphenylphosphino)ferrocene [27] were prepared as described in the literature. Di-2-pyrydyl ketone was purchased from Acros and used as received without further purification. Solvents were dried over appropriate reagents under dinitrogen and distilled immediately before use. Infrared spectra were recorded on a Hitachi I-2001 IR spectrometer. Fast-atom-bombardment (FAB) and electrospray ionization (ESI) mass spectra were recorded on a VG Blotch-5022 mass spectrometer and a Bruker APEX II mass spectrometer, respectively. \(^1\)H and \(^31\)P NMR spectra were obtained on a Varian Unity INOVA-500 spectrometer. Elemental analyses were performed at the National Chen-Kung University, Tainan, Taiwan.

3.2. Preparation of 1

\([\text{Cu}(\text{CH}_3\text{CN})_4][\text{BF}_4]\) (85 mg, 0.27 mmol) and Ph\(_2\)PC≡CPPh\(_2\) (168 mg, 0.43 mmol) were placed in an oven-dried 100 ml Schlenk flask, equipped with a magnetic stir bar and a rubber stopper. Freshly distilled CH\(_3\)CN (20 ml) was introduced into the flask via a syringe through the stopper. The mixture was stirred at room temperature for 18 h under dinitrogen. The solution was filtered, and the filtrate was concentrated to ca. 5 ml under vacuum. Diethyl ether (15 ml) was then carefully added to afford air-stable, colorless crystals of \([\text{Cu}(\text{dppa})_3(\text{CH}_3\text{CN})_2])[\text{BF}_4]_2\) (1) (197 mg, 0.126 mmol, 93% based on Cu atoms). Anal. Calc. for C\(_{82}\)H\(_{66}\)B\(_2\)Cu\(_2\)F\(_{8}\)N\(_2\)P\(_6\): C, 62.89; H, 4.25; N, 1.79. Found: C, 62.71; H, 4.15; N,
1.70%. Mass (FAB): m/z 654 ([Cu3(dppa)3]2+, 65Cu). 1H NMR (CD2Cl2, 20°C): δ 7.43–7.11 (m, 60H, Ph), 2.61 (s, 6H, CH3CN). 31P{1H} NMR (CD2Cl2, 20°C): δ = −26.70 (br).

3.3. Preparation of 2

[Cu(CH3CN)4][O2SCF3] (150 mg, 0.398 mmol) and Ph3PC≡CPPh2 (240 mg, 0.61 mmol) were placed in an oven-dried 100 ml Schlenk flask, and freshly distilled dichloromethane (30 ml) was introduced into the flask via a syringe. The mixture was stirred at room temperature for 14 h and then filtered. The filtrate was concentrated under vacuum to ca. 5 ml and diethyl ether (20 ml) was added to produce air-stable, colorless crystals of Cu2(dppa)3−

3.3. Preparation of 3

Compound 1 (25 mg, 0.015 mmol), 1,1'-bis(diphenylphosphino)ferrocene (23 mg, 0.041 mmol) and dichloromethane (8 ml) were placed in an oven-dried 100 ml Schlenk flask. The solution was stirred at room temperature for 8 h and filtered. Diethyl ether (15 ml) was added to give air-stable, orange crystals of [Cu2(dppa)-

3.5. Preparation of 4

Compound 1 (25 mg, 0.015 mmol), 1,1'-bis(diphenylphosphino)ferrocene (23 mg, 0.041 mmol) and dichloromethane (8 ml) were placed in an oven-dried 100 ml Schlenk flask. The solution was stirred at room temperature for 8 h and filtered. Diethyl ether (15 ml) was added to give air-stable, orange crystals of [Cu2(dppa)-

3.6. Structure determination for 1-4

A crystal of 1 (ca. 0.35 × 0.30 × 0.30 mm), 2 (ca. 0.25 × 0.25 × 0.20 mm), 3 (ca. 0.25 × 0.20 × 0.20 mm) and 4 (ca. 0.20 × 0.20 × 0.15 mm) was each mounted in a thin-walled glass capillary and aligned on the Bruker SMART Apex CCD (for 3 and 4) or the Nonius Kappa CCD (for 1 and 2) diffractometer with graphite-monochromated Mo Kα radiation (λ = 0.71073 Å). The maximum 2θ angle for data collection is 27.50° for all compounds. Of the 51 391, 40 329, 24 586 and 42 348 reflections collected for 1, 2, 3 and 4, 18 202, 8504, 8536 and 9857 reflections were independent, respectively. All data were corrected for Lorentz and polarization effects and for the effects of absorption. The structure was solved by the direct method.
