Antioxidant Activity of Tartary (Fagopyrum tataricum (L.) Gaertn.) and Common (Fagopyrum esculentum Moench) Buckwheat Sprouts

CHIA-LING LIU,† YIH-SHYUAN CHEN,† JOAN-HWA YANG,† AND BEEN-HUANG CHIANG*,‡

Department of Food Science, Nutrition and Nutraceutical Biotechnology, Shih Chien University, 70, Ta-chih St. Taipei 104, Taiwan, ROC and Institute of Food Science and Technology, National Taiwan University, No.1, Sec. 4, Roosevelt Road, Taipei 106, Taiwan, ROC

This study compared the differences of two types of buckwheat sprouts, namely, common buckwheat (Fagopyrum esculentum Moench) and tartary buckwheat (Fagopyrum tataricum (L.) Gaertn.), in general composition, functional components, and antioxidant capacity. The ethanol extracts of tartary buckwheat sprouts (TBS) had higher reducing power, free radical scavenging activity, and superoxide anion scavenging activity than those of common buckwheat sprouts (CBS). As for chelating effects on ferrous ions, CBS had higher values than TBS. Rutin was the major flavonoid found in these two types of buckwheat sprouts, and TBS was 5 fold higher in rutin than CBS. The antioxidant effects of buckwheat sprouts on human hepatoma HepG2 cells revealed that both of TBS and CBS could decrease the production of intracellular peroxide and remove the intracellular superoxide anions in HepG2 cells, but TBS reduced the cellular oxidative stress more effectively than CBS, possibly because of its higher rutin (and quercetin) content.

KEYWORDS: Buckwheat sprouts; flavonoids; antioxidant capacity; HepG2 cells

INTRODUCTION

Free radicals have been found to be related to illnesses, cell damages, cell death, and gene mutation (1), and the relationship between the intake of foods containing antioxidant components and the illnesses caused by oxidative damage has become an important research topic in the food and nutrition area. Buckwheat, an important staple food consumed in Japan, Korea, Russia, and Poland, is rich in polyphenols, including six flavonoids, rutin, orientin, vitexin, quercetin, isovitexin, and isoorientin (2–6). The chemical structures of these flavonoids can be found elsewhere (4–6). Among these antioxidant components, rutin was recognized as the most health protective and has also been proven to be anti-inflammatory and anticarcinogenic. Rutin also has relaxing effects on smooth muscles (7) and is effective for preventing capillary apoplexy and retinal hemorrhage (8, 2).

There are two types of buckwheat, common buckwheat and tartary buckwheat. Common buckwheat, or sweet buckwheat, is usually consumed in Asia, Europe, North America, South Africa, and Australia (2), whereas tartary buckwheat is rarely consumed because of its bitter taste. However, it has been reported that the general composition of crude protein, crude fiber, crude fat, and crude ash of common buckwheat and tartary buckwheat are essentially the same (9). Moreover, tartary buckwheat may even contain more bioactive components than common buckwheat. For instance, it has been reported that the flavonoid content of tartary buckwheat is higher than that of common buckwheat. The flavonoid content was 40 mg/g in tartary buckwheat seeds as compared to 10 mg/g in common buckwheat seeds (2). The comparative composition studies of common buckwheat and tartary buckwheat show higher thiamine, riboflavin, and pyridoxine contents, and they are an excellent food for use in preventative nutrition (10).

Bean sprouts, rich in dietary fibers, various nutrients, and bioactive components, are important vegetables consumed in Asian countries, and, nowadays, they have become more popular in the United States and European countries. Although the most popular bean sprouts are cultivated from mungbean and soybean, buckwheat seeds are also a good source of bean sprouts. However, little is known about buckwheat sprouts. The objective of this study was to investigate the differences between the two kinds of buckwheat sprouts, common buckwheat and tartary buckwheat, in general composition, functional components, and antioxidant capacity.

MATERIALS AND METHODS

Materials. Common buckwheat was supplied by Jingshan Farm of Taiwan, and tartary buckwheat was supplied by Erlin Farmers’ Association of Changhua, Taiwan. Rutin, quercetin, quercitrin, ascorbic...
acid, potassium ferricyanide, 1,1-diphenyl-2-picrylhydrazyl (DPPH), ferrozine, β-nicotinamide adenine dinucleotide (NADH), trypsin, 3-(4,5-dimethylthiazol-2-yl)-2,5-diphenyl-tetrazolium bromide (MTT), 2',7'-dichlorofluorescein diacetate (DCFH-DA), dihydroethidium (DHE), and dimethyl sulfoxide (DMSO) were purchased from Sigma Chemical Co. (St. Louis, MO, USA). Trichloroacetic acid, ferric chloride, and iron chloride tetrahydrate were purchased form Kanto Chemical Co. (Tokyo, Japan). Methanol and ethanol were purchased form J.T. Baker (Phillipsburg, NJ, USA). Ammonium thiocyanate and sodium phosphate were purchased form Shimakyo Co. (Osaka, Japan). Phenazine methosulfate (PMS) and nitro blue terazolium chloride monohydrate (NBT) were purchased form Acros Organics (Phillipsburg, N.J. USA). Vitexin was purchased from Fluka Co. (Darmstadt, Germany). Pyrogallol, ethylenediaminetetracetic acid, potassium chloride, potassium dihydrogen phosphate, sodium chloride, and sodium hydrogen carbonate were purchased form Merck Co. (Santa Ana, CA, USA). Isoorientin was purchased from Chromadex Co. (Ronkonkoma, NY, USA). Isovivetin was purchased from Fluka Chemika-Biochemika Co. (Buchs SG, Switzerland). The human hepatoma cell line (HepG2 cells) was a gift from Bioinformatics Laboratory., BCRC, Food Industry Research and Development Institute (Shinzu, Taiwan). Dulbecco’s Modified Eagle Medium (DMEM) was purchased from Invitrogen Corp. (Carlsbad, CA, USA). Fetal bovine serum (FBS) was purchased from Gemini Bio-Products (Woodland, CA, USA).

Cultivation of Buckwheat Sprouts. Buckwheat seeds, including common buckwheat and tartary buckwheat, were soaked in water for 6 h at room temperature and then put into a germination bag for germination in a shady, cool place for 12–15 h. The potting mix was laid on a plate (35 cm long by 25 cm wide by 3 cm high) with a perforated bottom. Once the buckwheat seeds were germinated, they were spread evenly on the potting mix, placed in a half-day sunny location, and watered every 4 h until the buckwheat sprouts were grown to a length of approximately 5 cm in 6–7 days. The sprouts were then harvested and immediately dried in a freeze-dryer (KINGMECH FD12–2S–6P–S, Kingmec Co., Taipei, Taiwan). The dried buckwheat sprout extracts were powdered by a high-speed pulverizer (250G, RT-04, Rong Tsong Precision Technology Co., Taichin, Taiwan), packed in plastic bottles, and stored in a freezer before analysis.

Composition Analysis of Buckwheat Sprouts. The ash, crude fat, crude protein, and crude fiber contents of dried samples were analyzed using the standard AOAC methods (11), and the compositions were denoted by percentage on dry basis.

Preparation of Ethanol Extracts of Buckwheat Sprouts. One hundred milliliters of 95% ethanol were added to 10 g of dried buckwheat powder, and the mixture was extracted by thermal reflux at 80 °C for 3 h and then filtered with Whatman No.1 filter paper. The above extraction was repeated twice, and the collected filtrate was evaporated at a temperature below 40 °C and dried in a freeze-drier to remove the water. Finally, the dried extracts were stored at −20 °C.

Phenolic Compound Analyses. A moderate amount of ethanol extracts from buckwheat sprouts were weighed and dissolved in methanol (12). After filtering the solutions through 0.45 μm nylon filters, samples were mixed with 1000 ppm of pyrogallol as internal standard for analysis by HPLC (Hewlett-Packard series 1100, Agilent Technologies, Inc., Santa Clara, CA, USA). The HPLC analysis was carried out under the following conditions; the Zorbax 80A Extend C18 column (5 μm, 4.6 × 250 mm) was used with water (Mill-Q, 18.2 MΩ) as mobile phase A, and methanol/acetic acid (95:5, v/v) was used as mobile phase B; the gradient elution was run with 20% of solution B at 10 min, 40% of solution B at 20 min, 50% of solution B at 30 min, 80% of solution B at 40 min, 80% of solution B at 50 min, and 100% of solution B at 60 min at a flow rate of 1 mL/min; the injection volume was 5 μL, and a wavelength of 254 nm was used for detection. Pure compounds including rutin, orientin, vitexin, quer cetin, quercetin, isovitexin, and isoorientin were also analyzed by HPLC with the same conditions, and the retention time was used to identify the flavonoids in the sample.

Determination of Reducing Power. The reducing power of the ethanol extracts of buckwheat sprouts were determined according to the method described by Oyaizu (13). Various concentrations (0.3–10 mg/mL) of the ethanol solutions of the buckwheat sprouts extracts and ascorbic acid were prepared, and 1 mL of each was mixed with 1 mL of 0.2 M phosphate buffer, pH 6.6, and 1 mL of 1% potassium ferricyanide [K₃Fe(CN)₆]. The mixture was then incubated at 50 °C for 20 min. The resulting solution was cooled down rapidly, spiked with 1 mL of 10% trichloroacetic acid and centrifuged at 1400g for 10 min. After centrifugation, 1 mL of supernatant was mixed with 1 mL of distilled water and 0.5 mL of 0.1% ferric chloride, and the absorbance was measured at 700 nm using a spectrophotometer. Increased absorbance of the reaction mixture indicated increased reducing power.

Determination of Free Radical Scavenging Activity. The effect of ethanol extracts of buckwheat sprouts on the DPPH radical scavenging activity was measured according to the method stated by Shimada et al. (14). Various concentrations (0.3–10 mg/mL) of the ethanol solutions of the buckwheat sprouts extracts and ascorbic acid were prepared, and 4 mL of each was mixed with 1 mL of freshly prepared 1 mM DPPH methanol solution. The solution without adding the DPPH solution served as a blank. The resulting solutions were then left to stand at room temperature for 30 min prior to being spectrophotometrically detected at 517 nm. Lower absorbance of the reaction mixture indicated higher free radical scavenging activity. The percentage of DPPH scavenging activity was expressed by \[1 - \left(\frac{\text{test sample absorbance}}{\text{blank sample absorbance}}\right)\] × 100%.

Determination of Metal Chelating Effect. The ferrous ions chelating effect was measured according to the method described by Dinis, Madeira, and Almeida (15). Various concentrations (0.3–10 mg/mL) of the ethanol solutions of the buckwheat sprouts extracts and ascorbic acid were prepared, and 2 mL of each was added to 0.1 mL of 1 mM FeCl₂ solution. The reaction was initiated by the addition of 0.2 mL of 2.5 mM ferrozine, shaken vigorously, and then left standing at room temperature for 10 min. The absorbance of solution was then measured spectrophotometrically at 562 nm. The percentage of ferrous ion chelating effect was expressed by \[1 - \left(\frac{\text{test sample absorbance}}{\text{blank sample absorbance}}\right)\] × 100%.

Determination of Superoxide Anion Scavenging Activity. The superoxide anion scavenging activity was measured based on the method described by Liu, Ooi, and Chang (16) with slight modification. Various concentrations (0.3–10 mg/mL) of the ethanol solutions of the buckwheat sprouts extracts were mixed with ascorbic acid and prepared. One milliliter of NBT solution (1.56 μM NBT in 100 mM phosphate buffer, pH 7.4), 1 mL of NADH solution (468 μM in 100 mM phosphate buffer, pH 7.4), and 0.1 mL of each of the prepared ethanol solutions were mixed. After adding 100 μL of PMS solution (60 μM PMS in 100 mM phosphate buffer, pH 7.4) to the mixture, the reaction mixture was incubated at 25 °C for 5 min, and the absorbance at 560 nm was measured against blank samples. Decreased absorbance of the reaction mixture indicated increased superoxide anion scavenging activity. The percentage inhibition of superoxide anion production was expressed by \[1 - \left(\frac{\text{test sample absorbance}}{\text{blank sample absorbance}}\right)\] × 100%.

Culture and Harvest of Human Hepatoma Cell Line. HepG2 cells were cultured with DMEM with 10% FBS in a T75 flask at 37 °C, 5% CO₂, and 90% relative humidity. To harvest cells, HepG2 cells were washed with PBS buffer and treated with 4 mL of trypsin-EDTA for 3 min. The reaction was stopped by adding 8 mL of DMEM with 10% FBS. The mixture was then transferred into a tube and centrifuged at 200g at room temperature for 5 min. After removing the supernatant, cell pellet was resuspended in 4 mL of DMEM with 10% FBS.

Cell Survival Test (MTT Assay). HepG2 cells (with an initial concentration of 1×10⁵ cells/well) were transferred and cultured into a 96-well plate at 37 °C and 5% CO₂ for 24 h. A 100 μL portion of buckwheat sprout ethanol extract (at 0.05–1 mg/mL) was then added to each well, and the mixture was incubated for 24 h. The incubation medium was then replaced with 100 μL of 2 mg/mL MTT (in PBS), and cells were incubated at 37 °C and 5% CO₂ for another 2.5 h. The MTT solution was then removed, 100 μL of DMSO was added into each well, and cells were incubated for 15 min in the dark. Finally, the absorbance of the cell sample was measured at 570 nm with an ELISA reader (Tecan Spectra, Wetzlar, Germany).
Determination of Intracellular Peroxide in HepG2 Cells. HepG2 cells (with an initial concentration of 4 × 10^4 cells/well) were transferred and cultured in a 6 cm^2 dish at 37 °C and 5% CO_2 for 24 h. Five milliliters of 0.5 mg/mL of buckwheat sprout ethanol extract was added into the dish, and then the contents were incubated at 37 °C and 5% CO_2 for 12 h. At 3, 6, 9, and 12 h, incubated solution was removed, 2 mL of 10 μM of DCFH-DA was added, and the sample was incubated for 30 min. The cells were then washed with PBS buffer, trypsinized, centrifuged, and resuspended in 0.7 mL of PBS buffer. To measure the intracellular peroxide, cell samples were analyzed at 485 nm by FACS Calibur (Becton Dickinson, San Diego, CA) equipped with Cell Quest software.

Determination of Intracellular Superoxide Anions in HepG2 Cells. HepG2 cells were cultured and treated with the ethanol extracts of buckwheat sprouts for 3, 6, 9, and 12 h, followed by the procedures described above. For measuring intracellular superoxide anions, 2 mL of 10 μM DHE was added into the dish, and cells were incubated at 37 °C and 5% CO_2 for 30 min. Cells were then harvested and resuspended. To measure the intracellular superoxide anion, cell samples were analyzed at 488 nm by FACS.

Statistical Analysis. Experimental results were presented as the mean ± standard derivation of three parallel measurements. The p values less than 0.05 were regarded as significant differences, and the p values less than 0.01 were very significant differences.

RESULTS AND DISCUSSION

Composition Analysis of Buckwheat Sprouts. The general composition of common buckwheat sprouts (CBS) and tartary buckwheat sprouts (TBS) were measured, and results are shown in Table 1. During cultivation, it was observed that CBS, especially their stems and leaves, were thicker and stronger than TBS. The results of analyses revealed that CBS had higher contents of crude protein, ash, and crude fat than TBS (P < 0.05). However, the content of crude fiber was not significantly different between these two types of buckwheat sprouts (P = 0.84). It has been reported that common buckwheat grain has more dietary fiber and less ash than tartary buckwheat grain and that tartary buckweed bran has more protein content than tartary buckweed bran (10).

Phenolic Compounds of Ethanol Extracts of Buckwheat Sprouts. The phenolic compounds in the ethanol extracts of CBS and TBS were analyzed by HPLC, and their chromatograms are shown in Figure 1. Four flavonoids, including rutin, isoroorientin, vitexin, and isovitexin, were found in the ethanol extract of CBS, whereas three flavonoids, rutin, quercetin, and quercetin, were found in TBS. Among these compounds, rutin was the major antioxidant component in both types of buckwheat sprouts. It is noteworthy that TBS contains only three closely related flavonoids. Rutin is a glycoside comprised of the flavonol quercetin and the disaccharide rutinose, and the glycoside quercetin is comprised of quercetin and rhamnose. All of them show remarkable antioxidant, anti-inflammatory, and anticancer activities. The ethanol extracts of TBS contains 655.82 mg/g of rutin, approximately 5 fold of the rutin content in the ethanol extracts of CBS (Table 2).

Antioxidant Capacity of Ethanol Extracts of Buckwheat Sprouts. The reducing power of the ethanol extracts from CBS and TBS were shown in Figure 2A. Results suggested that the higher the concentration of buckwheat sprout ethanol extracts, the higher their reducing power. The CBS ethanol extract had a higher reducing power than that of CBS (P < 0.01). At a concentration of 5 mg/mL, the reducing power of the ethanol extracts of buckwheat sprout was even higher than that of the ascorbic acid (data not shown). As shown in Figure 2B, the buckwheat sprout ethanol extracts had satisfactory scavenging effects on DPPH radicals. At low concentration (1.25 mg/mL) the CBS ethanol extracts had higher scavenging effects on DPPH radicals than that of CBS (P < 0.01). At a concentration of 5 mg/mL, the clearance of DPPH radicals for both CBS and TBS were approximately 88%. Ascorbic acid had a much higher free radical scavenging activity, and it reached approximately 93.1% at a concentration of 0.3 mg/mL. Similarly, the superoxide anion scavenging activity of CBS ethanol extracts was higher than that of CBS ethanol extracts (P < 0.01) (Figure 2C). At a concentration of 5 mg/mL, the ethanol extracts of TBS had a 19.1% clearing capacity, whereas CBS ethanol extracts had a value of 11.0% clearing capacity. It was also found that ascorbic acid had a relatively higher superoxide anion scavenging activity, which was approximately 45.0% at a concentration of 5 mg/mL.

Although the flavonoids, in general, possess ideal structure for antioxidant activity, the differences in chemical structures of different flavonoids would affect their antioxidant activities. It is known that the 3-OH group on the C ring plays an important role in flavonoid antioxidant activity, and maximum effectiveness for radical scavenging requires a 3-OH attached to the 2,3-double bond (17). However, the major flavonoids in CBS, including rutin, quercetin, and quercetin, all had their 3-OH group in the C ring blocked by rutinose, glucose, or rhamnose. Although the glycosylation would reduce the CBS flavonoid antioxidant activity, the presence of the two adjacent OH-groups in the ortho-diphenolic arrangement in the B ring certainly enhances their activity. The CBS flavonoids, including vitexin and isovitexin, have a lone 4′-OH group in the B ring, and thus, have lower antioxidant activity.

As shown in Figure 2D, the ethanol extracts of buckwheat sprouts had satisfactory chelating effects on ferrous ions, and the CBS chelating effects were greater than that of TBS (P < 0.01). At a concentration of 1.25 mg/mL, the CBS ethanol extracts had a 68.8% chelating effect, as compared with 45.0% in TBS. The two major points of attachment of ferrous ions to the flavonoids of buckwheat sprouts would be the 3′-OH in the C ring, and 4′-OH in the A ring. It is suspected that the glycosylation at 3-OH in the C ring of flavonoids greatly reduces TBS metal chelating ability. As for ascorbic acid, the chelating effect on metal ions was too weak to be detected.

Effects of Buckwheat on Cell Survival Test (MTT Assay). The cell survival test of HepG2 cells treated with different concentrations (at 0.05, 0.1, 0.2, 0.5, and 1 mg/mL) of buckwheat sprout ethanol extracts for 24 h were examined, and results are shown in Figure 3. The relative MTT activity of cells treated with 0.5 and 1 mg/mL of CBS ethanol extracts were 65.39 and 64.15%, respectively, whereas those of TBS

ethanol extracts were 65.66% and 52.65%, respectively ($P < 0.01$). TBS inhibited the growth of HepG2 cells more effectively than CBS, possibly because of its quercetin content, which is absent in CBS. Alia et al. (18) reported the effects of rutin and quercetin on cell growth and antioxidant activity of HepG2 cells. They found that cells were damaged even when treated with low dose of quercetin, but rutin had no cytotoxic effect on HepG2 cells at any dose for 24 h treatment. In this study, the cell survival rate was greater than 90% if the HepG2 cells were treated with buckwheat sprout ethanol extracts in the range of 0.05–0.2 mg/mL. Therefore, 0.2 mg/mL of the extracts was used to study their effects on antioxidant system in HepG2 cells for the following experiments.

### Effects of Buckwheat on Intracellular Peroxide and Superoxide Anions in HepG2 Cells

Production of intracellular peroxide in HepG2 cells treated with 0.2 mg/mL of ethanol extracts of buckwheat sprouts for 3–12 h are shown in Figure 4. The production of intracellular peroxide in HepG2 cells after treatment with the TBS ethanol extracts for 3 h was significantly inhibited ($P < 0.05$), but it was not inhibited by that of CBS.

* Each value was expressed as the mean ± standard deviation ($n=3$). ND: not detected. Values within a column superscripted with different letters were significantly different ($P < 0.05$).
As the treatment increased to 6 h, the production of intracellular peroxide in HepG2 cells reached to their lowest points for both TBS and CBS treatments, 66.0% and 76.5%, respectively. However, the inhibitory effects of TBS and CBS extracts on production of intracellular peroxide became less effective after 9 h.

The intracellular superoxide anions of HepG2 cells treated with 0.2 mg/mL of buckwheat sprout ethanol extracts for 3–12 h are shown in Figure 5. Compared to untreated cells, the intracellular superoxide anions in CBS and TBS treated cells were significantly lower ($P < 0.05$) for 6–9 h. However, there was no significant difference between untreated and treated cells after 12 h, and this data is consistent with the effect of buckwheat sprouts on intracellular peroxide as described above.

Figure 2. Antioxidant activities of CBS and TBS ethanol extracts. (A) Reducing power, (B) DPPH radical scavenging activity, (C) superoxide anion scavenging activity, and (D) Ferrous ion chelating power. (— ) Common buckwheat sprouts, (— — ) tartary buckwheat sprouts, (— — — ) ascorbic acid.

Figure 3. Dose–effects of CBS and TBS ethanol extracts on relative MTT activity in HepG2 cells. An asterisk indicates that the values are significantly different from untreated cells ($P < 0.05$).

It appeared that both TBS and CBS could protect HepG2 cells from antioxidative attack, and TBS was more effective than CBS. Alia et al. (19) also used human hepatoma HepG2 cells to study the antioxidant effects of quercetin and rutin, and they found that high doses of quercetin increased glutathione concentration, whereas rutin decreased the intracellular GSH at its highest concentration. Both quercetin and rutin decreased malondialdehyde and ROS generation in cells pretreated with tert-butyl hydroperoxide (t-BOOH). Kampkotter and co-workers (20) investigated the protective effects of quercetin and rutin on stress resistance in the organism Caenorhabditis elegans and found that the antioxidative activity of quercetin was higher than that of rutin under conditions of induced oxidative stress.
They suggested that, although rutin possesses antioxidative activity, quercetin acts as an antioxidant as well as a modulator of cellular signaling processes to exert its oxidative stress protection effect. In this study, it was found that the content of rutin in TBS was higher than that in CBS, and quercetin only existed in TBS (Table 2). Therefore, the finding that TBS is more effective in reducing the cellular oxidative stress in the human hepatoma HepG2 cells than CBS may be attributed to its higher rutin and quercetin contents.

This research found that rutin was the major flavonoid in both CBS and TBS and that it played an important role in the antioxidant capacity of buckwheat sprouts. TBS contained 5 fold the amount of rutin than CBS. Other than rutin, the major flavonoids in TBS include quercetin and quercitrin, and they all have two adjacent OH-groups in the ortho-diphenolic arrangement in the B ring. The flavonoids in CBS, including vitexin and isovitexin, have a lone 4′-OH group in the B ring, and, thus, TBS in general had a higher antioxidant capacity than CBS. The effects of buckwheat sprouts on the antioxidant system in HepG2 cells revealed that both buckwheat sprouts could significantly decrease the production of intracellular peroxide as well as remove the intracellular superoxide anions. However, probably due to the fact that the content of rutin in TBS was higher than that in CBS and that quercetin only existed in TBS, TBS was found to be more effective in reducing the cellular oxidative stress in the human hepatoma HepG2 cells than CBS. It appears that the tertiary buckwheat sprouts should be consumed more often because of its health-promoting properties. Cooking methods should be developed to render its bitter taste more tolerable.
