Abstract

The microwave dielectric, Bi$_{1.5}$ZnNb$_{1.5}$O$_7$ exhibits low-temperature dielectric relaxation. To find the origin of the dielectric relaxation of Bi$_{1.5}$ZnNb$_{1.5}$O$_7$, we studied the structure and dielectric behavior of Bi$_{1.5}$ZnNb$_{1.5}$O$_7$ in detail. The Bi$_{1.5}$ZnNb$_{1.5}$O$_7$ is not composed of a single phase pyrochlore structure. Instead, it consists of unusual structure of Bi$_{1.5}$Zn$_{0.92}$Nb$_{1.5}$O$_{6.92}$ and ZnO. The ZnO is distributed evenly in the grain and at the boundary of the Bi$_{1.5}$Zn$_{0.92}$Nb$_{1.5}$O$_{6.92}$ structure. Many small voids (<1 μm) were observed in the samples due to the loss of volatile Bi during sintering. The Bi$_{1.5}$Zn$_{0.92}$Nb$_{1.5}$O$_{6.92}$ exhibited a broad dielectric relaxation between 100 and 400 K at 1.8 GHz, peaking around 230 K. The Fourier transformation IR spectra predict that dielectric relaxation may occur near room temperature during extremely high frequencies (THz). The substitutional point defects in Bi$_{1.5}$Zn$_{0.92}$Nb$_{1.5}$O$_{6.92}$ provide room for dielectric relaxation at microwave frequencies. The low quality factor $Q \times f$ (∼520 GHz) of Bi$_{1.5}$Zn$_{0.92}$Nb$_{1.5}$O$_{6.92}$ results from both the dielectric relaxation of the material and the voids within its microstructure. The presence of ZnO phase in the Bi$_{1.5}$ZnNb$_{1.5}$O$_7$ produces interstitial defects that further enhance the dielectric relaxation with reduced quality factor $Q \times f$ (∼426 GHz).

Keywords: Powders-solid state reaction; Dielectric properties; Microstructure

1. Introduction

The demands for miniaturization in microwave communication technologies require continual discovery and innovation in the development of new materials. Most conventional ceramics have excellent microwave dielectric properties, such as BMT (BaMg$_{1/3}$Ta$_{2/3}$O$_3$), BNT (BaO-Nd$_2$O$_3$-TiO$_2$), etc., and sinterabilities above 1300°C. Considering the high sintering temperature, Ag–Pd electrode is the only choice for multilayer ceramic components (MLCCs). In the microwave frequency range, the dielectric loss of components is mostly attributed to the electrode. Good conductivity of the electrode is important for MLCCs. Thus, it is desirable to replace the poorly conducting and high-cost Ag–Pd electrode with silver electrodes which have better properties and lower cost. However, since the melting temperature of silver is low (961°C), a low sintering temperature material is required to cofire with silver.

Recently, Bi$_{1.5}$ZnNb$_{1.5}$O$_7$ (BZN) has emerged as a good low-sintering (~1000°C) microwave material because it exhibits high dielectric constant and low-temperature coefficient of resonance frequency ($\tau_f$).$^{1,2}$ Its sintering temperature can be decreased to 950°C by adding 3.0 wt% BaCO$_3$–CuO into BZN$^8$ and even lower to 850°C by adding 2 mol% V$_2$O$_5$ to BZN.$^9$ However, BZN exhibits low temperature (0–200 K) dielectric relaxation behavior at 1 MHz. Upon heating, the relaxation frequency steeply increases according to the Arrhenius law and appears in microwave range at room temperature.$^{10,11}$

Levin et al.$^{12}$ investigated the structure of Bi$_{1.5}$ZnNb$_{1.5}$O$_7$ that is composed of an unusual cubic pyrochlore single phase consisting of Bi$_{1.5}$Zn$_{0.92}$Nb$_{1.5}$O$_{6.92}$ and small amounts of ZnO. In order to find the origin of the dielectric relaxation of Bi$_{1.5}$Zn Nb$_{1.5}$O$_7$, we studied the structures and dielectric behaviors of Bi$_{1.5}$ZnNb$_{1.5}$O$_7$ in detail. The results are compared with that of Bi$_{1.5}$Zn$_{0.92}$Nb$_{1.5}$O$_{6.92}$.

2. Experimental

Reagent grade oxide powders with an appropriate molar ratio of Bi$_2$O$_3$, ZnO, and Nb$_2$O$_5$ (99.9% purity each, Alfa Chemicals,
USA) were used to prepare BZN samples using the conventional mixed solid method. The samples were calcined at 900 °C for 2 h. The crystalline phases of the calcined BZN powder samples were comparable to those reported in the literature.9,10

The BZN powder was characterized by light scattering (Zetasizer 3000HS, Malvern Instruments, UK) for particle size, BET for surface area (Micrometrics, ASAP2000 BET, USA), electronic probe microanalyzer (EPMA, Joel, JXA-8600SX, Japan) for chemical composition, and X-ray diffractometer (XRD, PW 1830, Philips, Netherlands) for the crystalline structure. The BZN powder was pressed at 500 kg/cm² to form tablets (8 mm diameter) and sintered at 1050 °C for 4 h. The distribution of elements in sintered tablets was observed using an electronic probe microanalyzer. The microstructures of sintered samples were evaluated by scanning electron microscopy (SEM) equipped with wavelength dispersive spectrometer (WDS) (Joel, JSM-T100, Japan).

The dielectric properties of sintered BZN tablets were evaluated by Impedance Analyzer (Hewlett Packard, 4291B, USA) in the frequency range of 1 MHz–1.8 GHz and Network Analyzer (Hewlett Packard, 8722ES, USA) in the microwave frequency region. THz measurement (200–750 GHz) was performed using a custom-made time domain THz spectrometer with femtosecond laser system (Quantamond, Odin). Two identical 1 mm [1 1 0] ZnTe single crystals were used to generate (optical rectification) and detect (electro-optic sampling) the THz pulses. Infrared reflectivity spectra were obtained using a Fourier transform spectrometer (Bukker IFS 11v, Germany) in the frequency range of 20–3300 cm⁻¹ (0.6–100 THz).

3. Results and discussion

The physical and chemical properties of Bi1.5Zn0.92Nb1.5O7 powders prepared by the solid mixing method are summarized in Table 1. They have comparable surface areas and particle size. The content of bismuth in both BZN powders was slightly reduced after calcination at 900 °C for 2 h. This might be due to the volatility of bismuth. Despite this, the stable cubic pyrochlore phase was preserved in both samples as shown in their XRD spectra (Fig. 1). Extra XRD peaks of ZnO are observed in the Bi1.5ZnNb1.5O7 sample in both samples as shown in their XRD spectra (Fig. 1). Extra XRD peaks of ZnO are observed in the Bi1.5ZnNb1.5O7 sample in both samples as shown in their XRD spectra (Fig. 1). Extra XRD peaks of ZnO are observed in the Bi1.5ZnNb1.5O7 sample in both samples as shown in their XRD spectra (Fig. 1).

In order to obtain the distribution of elements in two samples, we used the EPMA technique to map the samples. The metal elements of Bi1.5Zn0.92Nb1.5O7 are distributed uniformly in the sample as shown in Fig. 2. There is a slight Zn element congregation in the sample of Bi1.5Zn0.92Nb1.5O7 as shown in the upper right corner of Fig. 3. Table 2 summarizes the results of EPMA-WDS chemical composition analysis of two materials at different locations within the samples. It is interesting to note that in both the samples there are no differences in the grain or at its boundary. Both Bi1.5Zn0.92Nb1.5O7 and Bi1.5ZnNb1.5O7 crystals exhibit many small voids (<1 μm) which is likely from the loss of volatile Bi during sintering (reduced from 1.43 to 1.42 mol).

In the structure of Bi1.5Zn0.92Nb1.5O7, 21% of Bi3⁺ atoms are replaced with Zn²⁺ atoms, and 4% of the A position remains vacant (substitutional point defects) that provides room for dielectric relaxation.16 The temperature dependence of real and imaginary part on the dielectric function for Bi1.5Zn0.92Nb1.5O7 is shown in Fig. 4. The dielectric relaxation occurs between 100 and 230 K. The relaxation frequency is shifted to a higher temperature. The presence of dielectric relaxation will result in high microwave dielectric loss. We have observed a low Q × f (less than 600) experimentally in the samples at 2.2 GHz (Table 3).

Experimental room temperature infrared reflectivity spectrum of Bi1.5Zn0.92Nb1.5O7 with its fit is shown in Fig. 5(a). The spectral range above 1000 cm⁻¹ is not shown because the reflectivity is flat at frequencies approaching the value given by the high-frequency permittivity ε∞. The complex dielectric response ε*(ω) in the infrared range can be obtained from the reflectivity R(ω) spectra via formula13:

$$R(\omega) = \frac{\sqrt{\varepsilon(\omega)} - 1}{\sqrt{\varepsilon(\omega)} + 1}$$  (1)

Using the fit procedure of $\varepsilon^*(\omega)$. A generalized oscillator model with the factorized form of the complex dielectric function was used:

$$\varepsilon^*(\omega) = \varepsilon'(\omega) + i\varepsilon''(\omega) = \varepsilon_\infty \prod_{j=1}^{n} \frac{\omega_j^2 - \omega^2 + i\gamma_j\omega}{\omega_j^2 - \omega^2 + i\gamma_j\omega}$$

(2)

$\omega_j^2$ and $\omega_j^2$ denote the transverse optical (TO) and longitudinal optical (LO) frequencies of the $j$th polar mode, respectively, and $\gamma_j$ and $\gamma_j$ are the corresponding damping constants. $\varepsilon_\infty$ denotes high-frequency permittivity originating from electron transitions. The results of the fittings are shown in Fig. 5(a) by dotted lines.

Fig. 4. Temperature dependence of dielectric permittivity at selected frequencies between 3 MHz and 1.8 GHz: (a) real part and (b) imaginary part of dielectric permittivity for Bi$_{1.5}$Zn$_{0.92}$Nb$_{1.5}$O$_{6.92}$.

Fig. 5. FTIR and THz spectra of Bi$_{1.5}$Zn$_{0.92}$Nb$_{1.5}$O$_{6.92}$: (a) infrared reflectivities at 300 K, (b) the real part of permittivity, and (c) the imaginary part of permittivity calculated from the fits to the reflectivities and submillimeter data with Eqs. (1) and (2).
The real part $\varepsilon'$ (ω) and imaginary part $\varepsilon''$ (ω) of complex permittivity obtained from the fit are shown in Fig. 5(b) and (c) together with experimental THz spectra. The more accurate experimental THz dielectric data were used to fit the infrared reflectivity data of $\text{Bi}_1.5\text{Zn}_0.92\text{Nb}_1.5\text{O}_6.92$ in the range of 6-30 cm$^{-1}$. Fig. 5(c) also shows that the oscillator fit is not suitable for description of the THz data below 10 cm$^{-1}$. The relaxation is probably broader and should be in fact fitted with the distribution of relaxation frequencies and not by overdamped oscillator how it is in our case. The submillimeter permittivity $\varepsilon''$ is lower than the permittivity below 2 GHz which gives evidence about the presence of microwave relaxation. This broad relaxation was also seen in $\text{Bi}_1.5\text{Zn}_0\text{Nb}_1.5\text{O}_7$ and fitted in Ref. 11 with distribution of relaxations. Levin et al. 12 have shown that the Bi and Zn atoms in the A sites and some O atoms are dynamically disordered among several local potential minima, and Kamba et al. 13 have assigned the relaxation to the local hopping of these disordered atoms. Ref. 11 is devoted to $\text{Bi}_1.5\text{Zn}_0\text{Nb}_1.5\text{O}_6.92$; however, later structural studies of Levin et al. 12 revealed that the sample actually consisted of $\text{Bi}_1.5\text{Zn}_0\text{Nb}_1.5\text{O}_6.92$ and small amounts of ZnO.

We note the broad absorption peak near 30 cm$^{-1}$ in $\varepsilon''(ω)$ spectrum in Fig. 5(c). It fits to overdamped oscillator and gives evidence about large structural disorder in the BZN lattice. Parameters of the oscillator fit are similar to those already published in Refs. 11, 14. The results indicate that the polar phonon modes are not influenced by small content of ZnO second phase. The dielectric properties of $\text{Bi}_1.5\text{Zn}_0\text{Nb}_1.5\text{O}_7$ and $\text{Bi}_1.5\text{Zn}_0\text{Nb}_1.5\text{O}_7.0.02\text{V}_2\text{O}_5$ at high frequencies are listed in Table 3. Both materials reveal high dielectric constant and low $Q\times f$. Their microwave properties are very similar even when changing the sintering temperatures. However, $\text{Bi}_1.5\text{Zn}_0\text{Nb}_1.5\text{O}_7$ exhibits a $Q\times f$ than that of $\text{Bi}_1.5\text{Zn}_0\text{Nb}_1.5\text{O}_7.0.02\text{V}_2\text{O}_5$ especially for the sample sintered at 1050 °C for 4 h. The excess ZnO in $\text{Bi}_1.5\text{Zn}_0\text{Nb}_1.5\text{O}_7$ may produce interstitial defects appearing in the cubic pyrochlore crystalline structure. Such defects would reduce the $Q\times f$ of $\text{Bi}_1.5\text{Zn}_0\text{Nb}_1.5\text{O}_7$.

4. Conclusions

Ceramics of $\text{Bi}_1.5\text{Zn}_0\text{Nb}_1.5\text{O}_7$ and $\text{Bi}_1.5\text{Zn}_0\text{Nb}_1.5\text{O}_7.0.02\text{V}_2\text{O}_5$ were successfully prepared. Our microstructure study of $\text{Bi}_1.5\text{Zn}_0\text{Nb}_1.5\text{O}_7$ shows that it consists of cubic pyrochlore structure of $\text{Bi}_1.5\text{Zn}_0\text{Nb}_1.5\text{O}_6.92$ and small amounts of ZnO. For pure $\text{Bi}_1.5\text{Zn}_0\text{Nb}_1.5\text{O}_6.92$, a broad dielectric relaxation that peaks around 230 K was observed at 1.8 GHz, which is similar to the relaxation of $\text{Bi}_1.5\text{Zn}_0\text{Nb}_1.5\text{O}_7$ seen in Ref. 11. Nevertheless, the $\text{Bi}_1.5\text{Zn}_0\text{Nb}_1.5\text{O}_6.92$ has systematically slightly higher $Q\times f$ than that of $\text{Bi}_1.5\text{Zn}_0\text{Nb}_1.5\text{O}_7$. It is probably due to interstitial defects from ZnO second phase presented in $\text{Bi}_1.5\text{Zn}_0\text{Nb}_1.5\text{O}_7$. Highly disordered pyrochlore structure results not only in broad microwave dielectric relaxation but also in broad excitation in submillimetre range, which is probably activated phonon density of states in FTIR and THz spectra. Both $\text{Bi}_1.5\text{Zn}_0\text{Nb}_1.5\text{O}_7$ and $\text{Bi}_1.5\text{Zn}_0\text{Nb}_1.5\text{O}_7.0.02\text{V}_2\text{O}_5$ reveal high dielectric constant (>120) and low $Q\times f$ (<600) at 2.2 GHz. The low $Q\times f$ results from the dielectric relaxation and voids present in the samples.

Acknowledgments

Financial support obtained from the National Science Council of Republic of China (NSC91-2622-E-007-032, NSC92-2120-E-002-002, and NSC93-2120-M-002-010), and Academy of Sciences of the Czech Republic (A1010213) is highly appreciated.
