In this study, *Lactobacillus paracasei* subsp. *paracasei* NTU101 and *Lactobacillus plantarum* NTU 102 were used as starter to ferment soy–skim milk, and the optimal mixing ratio was evaluated. The influence of lactic acid bacteria (LAB)-fermented soy–skim milk on mucosal integrity in a gastric mucosal lesion rat model was also investigated. After 24 h, cell densities of *L. paracasei* subsp. *paracasei* NTU 101 and *L. plantarum* NTU 102 fermented in 75% soy milk and 25% milk (optimal condition) were 1.2×10^9 and 2.5×10^9 CFU/mL. After 180 days at 4 °C, the cell densities of the freeze-dried powders of the fermented soy–skim milks were 1×10^9 CFU/g; slight variations in pH and acidity were observed. Pylorus ligation with acidified ethanol treatment was used as the gastric lesion animal model. LAB-fermented soy–skim milk reduced the gastric lesion index and the lipid peroxides (LPO) of gastric mucosa and serum. Administration of the fermented soy–skim milk enhanced superoxide dismutase (SOD) activity and prostaglandin E₂ (PGE₂) synthesis. Therefore, LAB-fermented soy–skim milk at 10^9 CFU/day protects against gastric injury.

KEYWORDS: Fermented soy–skim milk; acute gastric lesion; pylorus ligation combined with acidified ethanol

INTRODUCTION

Lactic acid bacteria (LAB) have health-promoting attributes, including antimutagenic and anticarcinogenic activities, hypocholesterolemic properties, and antagonistic actions that can restrain intestinal and foodborne pathogens and immunomodulation effects. LAB have been reported to improve gastrointestinal health. Furthermore, LAB and their fermented products can effectively enhance the integrity of the gastric mucosa. Many reports suggest that LAB and their fermented products have protective effects against mucosal injury in the stomach. Yogurt containing *Lactobacillus gasseri* OLL2716 (LG21 yogurt), which can enter the gastric mucus layer (1), has been shown to be effective in suppressing *Helicobacter pylori* and reducing gastric mucosal inflammation in humans (2). In 2004, Uchida and Kurakazu reported that the ingestion of LG21 yogurt by rats could increase prostaglandin E₂ (PGE₂) generation in the gastric mucosa, which led to the prevention of gastric ulcers (3). *Lactobacillus rhamnosus* GG (LGG) has also been reported to enhance gastric healing by activation of epidermal growth factor receptor (EGF receptor) and up-regulation of the expression of ornithine decarboxylase (ODC), B-cell lymphoma 2 (Bcl-2), and vascular endothelial growth factor (VEGF) in ulcerated tissues (4).

Soybeans are a source of dietary peptides, which have anti-hypertensive, anticholesterol, and antioxidative properties and may prevent various types of cancer. Soy milk is a traditional Chinese beverage made from soybean. Some reports have shown potential health benefits of ingesting soy milk in preventing and slowing the progression of prostate cancer (5).

Our laboratory has found two LAB strains native to Taiwan. These strains, *Lactobacillus paracasei* subsp. *paracasei* NTU 101 (6) and *Lactobacillus plantarum* NTU 102 (7), were isolated from human feces and homemade Korean-style cabbage pickles. These bacteria can resist gastric juice and bile salt. They also have probiotic characteristics that are effective in reducing cholesterol in the blood and liver (8). After ingestion of *L. paracasei* subsp. *paracasei* NTU 101, up-regulation of the antigen-presenting ability of dendritic cells and expression of natural killer group-2 D (NKG2D) molecules capable of triggering natural killer cell-mediated cytotoxicity were observed. Lymphocyte proliferation and antibody production were also significantly increased in mice after treatment (9). Fermented soy–skim milk supplemented with or without *Momordica charantia* and *L. paracasei* subsp. *paracasei* NTU 101 is effective in preventing and slowing hyperlipidemia-induced oxidative stress and atherosclerosis (10). *L. plantarum* NTU 102 has also been shown to induce increased activity of superoxide dismutase (SOD) and phenol oxidase (PO) as part of the immune response to *Litopenaeus vannamei* (11). The aim of the present study was to investigate the antiulcer activity of

Figure 1. Growth of *L. plantarum* NTU 102 fermented with different ratios of soy milk and skim milk. Inoculum volume = 3%; static incubation at 37 °C.

LAB-fermented soy–skim milk on the mucosal defense system. Pylorus ligation combined with acidified ethanol treatment was used as an animal model of gastric lesion.

MATERIALS AND METHODS

Chemicals and Media. Acetic acid, *n*-butanol, glycerol, histamine, indomethacin, methanol, *o*-phthalaldehyde (OPA), sodium chloride, sodium dodecyl sulfate (SDS), and 1,1,3,3-tetramethoxypropane (TMP) were purchased from Sigma Chemical Co. (St. Louis, MO). Agar and gelatin digest peptone were purchased from Alpha Biosciences (Baltimore, MD). Lactobacilli MRS broth was purchased from Difco Co. (Detroit, MI).

Preparation of Soy–Skim Milk and Fermented Soy–Skim Milk by LAB and Analytical Assays. The preparation of soy–skim milk and fermented soy–skim milk by LAB was described as follows: Skim milk at 8% (w/v) was reconstituted with Anchor skim milk powder (Fonterra Ltd., Auckland, New Zealand). The skim milk was treated individually in a water bath at 90 °C for 1 h. The nongenetically modified sugar-free soy milk was purchased from a local supermarket (Chuan Kui Yuba Factory, Taipei, Taiwan) and autoclaved for 15 min at 121 °C as described by Chou and Hou (12). After heat treatment and cooling to room temperature, skim milk and soy milk were mixed in various proportions of 0:100, 25:75, 50:50, 75:25, and 100:0, respectively.

Figure 2. Shelf-life studies: changes of cell count, pH value, and titratable acidity in fermented soy–skim milk freeze-dried powder during the storage period. Medium, 75% soy milk + 25% skim milk; inoculum volume, 3%; storage at 4 °C.

L. paracasei subsp. *paracasei* NTU 101 and *L. plantarum* NTU 102 were inoculated at 1% on lactobacilli MRS broth and transferred monthly. Furthermore, these strains were inoculated in soy–skim milk at 37 °C for 0–48 h, respectively which was lyophilized by Bench Tops3R (Virtis Co., Gardiner, NY) and stored at 4 °C prior to use. During incubation, samples were taken at 0, 4, 8, 12, 24, and 48 h for testing of pH, culture growth, and titratable acidity. The pH of the sample was measured with a pH-meter (MP2000, Mettler Toledo, Greifensee, Switzerland). MRS agar was used to enumerate *L. paracasei* subsp. *paracasei* NTU 101 and *L. plantarum* NTU 102, respectively. Plates were incubated in an ordinary incubator at 37 °C for 2 days. The colonies appearing on the plates were counted. Titratable acidity was determined using the method described in section 37.1.37 of AOAC, 1997.

Shelf-Life Studies. The shelf life of the fermented soy–skim milk with the highest mean score of overall acceptability was assessed. The freeze-dried powder of fermented soy–skim milk by LAB was stored at 4 °C for 6 months and then evaluated for pH, culture viability, and titratable acidity.

Animal Grouping and Experiment Schedule. Male Wistar rats about 4 weeks of age were obtained from the Laboratory Animal Center of National Taiwan University, College of Medicine. They were kept in a temperature-controlled room (25 °C) with a maintained relative humidity of 60% under a 12 h light/12 h dark cycle (light on at 9:00 a.m.). Food and water were given freely each day. The experiment was reviewed and approved by the Animal Care and Research Ethics Committee of the National Taiwan University. In the experiment, 56 rats were randomly

^a Control, normal diet; yogurt, commercial yogurt diet; soy-skim milk, nonfermented soy-skim milk; 101-8, 10⁸ CFU/day of soy-skim milk fermented by *L. paracasei* subsp. *paracasei* NTU 101; 101-9, 10⁹ CFU/day of soy-skim milk fermented by *L. paracasei* subsp. *paracasei* NTU 101; 102-8, 10⁸ CFU/day of soy-skim milk fermented by *L. plantarum* NTU 102; 102-9, 10⁹ CFU/day of soy-skim milk fermented by *L. plantarum* NTU 102. Data are presented as mean ± SEM (*n* = 8); numbers with different letters within the same column are significantly different (*p* < 0.05).

divided to 7 groups including (1) administration of water (control), (2) administration of commercial yogurt (yogurt), (3) administration of nonfermented soy-skim milk (soy-skim milk), (4) administration of 10⁸ CFU/day of soy-skim milk fermented by *L. paracasei* subsp. *paracasei* NTU 101 (101-8), (5) administration of 10⁹ CFU/day of soy-skim milk fermented by *L. paracasei* subsp. *paracasei* NTU 101 (101-9), (6) administration of 10⁸ CFU/day of soy-skim milk fermented by *L. plantarum* NTU 102 (102-8), and (7) administration of 10⁹ CFU/day of soy-skim milk fermented by *L. plantarum* NTU 102 (102-9).

Rats were fed for 28 continuous days; 24 h before surgery and sacrifice, all food was removed. The animals were anesthetized by sodium pentobarbital (SCI Pharmtech, Taoyuan, Taiwan) and pylorus ligation (13) combined with acidified ethanol (0.15 N HCl and 70% ethanol mixture) (14) for 1 h. Animals were euthanized by carbon dioxide inhalation. Gastric juices were collected, and their pH, volume of gastric acid, and total gastric acidity were evaluated (13). The stomach tissue was cut open and cleaned frequently with 0.8% sodium chloride solution and examined for ulceration and damage by microscopic examination of a stomach biopsy. Gastric mucosa was collected on the surface of the stomach and stored at -80 °C for the assay of SOD activity, thiobarbituric acid reactive substances (TBARS), and PGE₂.

Determination of the Level of Mucosal SOD. The SOD activities of homogenate supernatant of gastric mucosa from rats were examined using the RANSOD commercial kit (Randox Laboratories Ltd., Crumlin, U.K.) (10).

Determination of the Level of Mucosal TBARS. TBARS levels of gastric mucosa were determined according to the method of thiobarbituric acid (TBA) colorimetric analysis, and the optical density (OD) value was measured at 532 nm. Lipid peroxidation (LPO) in the supernatant of gastric mucosa homogenate was estimated in terms of TBARS with modification (15). TBARS level was expressed in nanomoles per gram of wet tissue. A standard curve was prepared by diluting well-known concentrations (0, 1.5625, 2.5, 3.125, 6.25, and 12.5 nmol/L) of TMP in 0.01 N HCl.

Determination of the Level of Mucosal PGE₂. Gastric mucosal tissues were homogenized and centrifuged, and the supernatant was used for PGE₂ determination using a PGE₂ enzyme immunoassay (EIA) kit (Amersham Bioscience, Little Chalfont, U.K.) according to the manufacturer's instruction. PGE₂ level was expressed in picograms per milligram of protein, where the protein concentration was measured by NanoDrop 1000 spectrophotometer (Thermo Scientific) (16).

Study on Morphology and Histology of the Stomach. The morphology of the stomach was evaluated (17). Images were analyzed by ImageJ (ImageJ 1.38x, Rasband, WS; U.S. National Institutes of Health, Bethesda, MD), and the ulcer index was calculated by using the equation ulcer index = 10/*X*, where *X* = total mucosal area/ulcerated area. Pathological tissues were entrusted to the Laboratory Animal Center of National Taiwan University, College of Medicine.

Statistics. Data are expressed as the mean ± SEM. The statistical significance in the behavioral and biochemical effects was determined by one-way ANOVA, followed by ANOVA with Duncan's multiple-range tests.

Figure 3. Image analysis of gastric lesion. Rats fed yogurt, soy-skim milk, and fermented soy-skim milk for 4 weeks after pylorus ligation combined with acidified ethanol induced acute gastric lesions of gastric mucosa (left); the same images after optimized background subtraction by ImageJ software (right).

RESULTS

Growth of *L. plantarum* NTU 102 Fermented in Soy-Skim Milk. After 24 h of fermentation with *L. plantarum* NTU 102, the titratable acidity of the mixture of 75% soy milk and 25% skim milk was highest of all the groups. The cell densities of each group were similar (10⁹ CFU/mL) (Figure 1). We used the 75% soy milk and 25% skim milk mixture as the optimal medium for fermentation by *L. plantarum* NTU 102.

Shelf-Life Studies. The results of the shelf-life studies are shown in Figure 2. After storage for 180 days at 4 °C, the cell densities in the freeze-dried powders of soy-skim milk fermented by *L. paracasei* subsp. *paracasei* NTU 101 and *L. plantarum* NTU 102 were at 1 × 10⁹ CFU/g. There were slight variations in pH and titratable acidity. The samples were stable at 4 °C.

Change in Body Weight and Daily Intake of Experimental Rats. The body weight and daily intake of the experimental rats increased normally and did not differ among the groups during the experiment (data not shown). In addition, the externals and health of all experimental animals had a normal expression.

Figure 4. Changes of LPO (A), SOD activity (B), and PGE₂ level (C) of the gastric mucosa in rats fed yogurt, soy-skim milk, and soy-skim milk fermented by *L. paracasei* subsp. *paracasei* NTU 101 and *L. plantarum* NTU 102 for 4 weeks after pylorus ligation combined with acidified ethanol induced acute gastric lesions. Bars with different letters are significantly different ($p < 0.05$).

Gastric Acid Parameters and Gastric Lesion Index. Of all of the experimental groups, the gastric juice of the 101-9 group had the lowest pH ($p < 0.05$) (Table 1). Feeding rats with soy-skim milk fermented with *L. plantarum* NTU 102 (102-8 and 102-9 groups) reduced the volume of gastric acid. The total gastric acidity was not different among groups ($p < 0.05$). With regard to the gastric lesion index, microscopical findings of the gastric mucosal are shown in Figure 3. The lesion indices in the control group and the nonfermented soy-skim milk group were not different ($p < 0.05$) (Table 1). Groups 101-8, 102-8, and 102-9 were not significantly different from the control group (1.01 ± 0.18). There was dose-dependent inhibition of acute gastric lesions in the 101-9 group, and significant differences were observed.

Effects of LAB-Fermented Milk on LPO and SOD Activities in the Gastric Mucosa. LPO activity was increased in the control group. Feeding with commercial yogurt, nonfermented

Figure 5. Histological studies of gastric mucosa of rats fed yogurt, soy-skim milk, and soy-skim milk fermented by *L. paracasei* subsp. *paracasei* NTU 101 and *L. plantarum* NTU 102 for 4 weeks after pylorus ligation combined with acidified ethanol induced acute gastric lesions rats (400 $\times$).

soy-skim milk, and fermented soy-skim milk (groups 101-8, 101-9, 102-8, and 102-9) reduced the level of LPO in the gastric mucosa (Figure 4A). SOD activity was decreased in rats that received pylorus ligation combined with acidified ethanol. There was no significant difference in SOD activity between the control group and the groups which received commercial yogurt or nonfermented soy-skim milk (101-8 and 102-8). In contrast, groups 101-9 and 102-9 had enhanced SOD activity in the gastric mucosa (Figure 4B).

Effects of LAB-Fermented Milk on PGE₂ Generation in the Gastric Mucosa. In the control group, PGE₂ generation in the gastric mucosa was 3036.16 pg/mg of protein. Groups 101-9 and 102-9 had significantly increased PGE₂ generation (5408 and 5340 pg/mg of protein, respectively, $p < 0.05$) (Figure 4C). Although there was no significant difference in biochemical analysis between group 101-8 and the control group, there was a trend of increasing levels of PGE₂ in group 101-8.

Histological Study. Rats fed commercial yogurt and soy-skim milk fermented by *L. paracasei* subsp. *paracasei* NTU 101 and *L. plantarum* NTU 102 (10^9 CFU/day) had normal mucosal structure. Mucosal structures were significantly different in the group that received water or nonfermented soy-skim milk (Figure 5).

DISCUSSION

Stomach ulcers, a modern disease, are caused by regular smoking, use of alcohol, exposure to chemicals and toxic substances, and acid stress, all of which indirectly affect food digestion and absorption, functions that both have tremendous impact on human health (18). Recent studies in rats have shown that some foods, such as fruits and vegetables, have strong preventive effects on gastric ulcers induced by HCl or ethanol (19). Dairy foods are also recommended as therapy for patients with peptic ulcer. In 1984, Matera et al. reported that prostaglandins in milk may be responsible for its beneficial effects in the prevention of peptic ulcer in rats by using a cold-restraint stress-induced ulcer model (20). Dial and Lichtenberger demonstrated that milk and its phospholipids have antiulcer activity against acute gastric lesions induced by 0.6 M HCl (21). Furthermore, the

lipid and nonlipid fractions of dairy foods possess gastroprotective activity against stress-induced ulcer in rats (22). In contrast, Ippoliti et al. reported that the proteins and calcium in milk, which stimulate gastric acid secretion, are not suitable for patients with peptic ulcer (23). However, milk has been reported to be effective for ulcer healing.

High intake of fermented milk products may decrease the risk for ulcer (24). LAB-fermented milk also has strong antiulcer properties on gastric lesions. In 2001, Sakamoto et al. reported that LG21 was effective in suppressing *H. pylori* and reducing gastric mucosal inflammation (2). Uchida and Kurakazu reported that LG21 yogurt significantly and dose-dependently inhibited the formation of acute gastric lesions caused by 0.6 M HCl in rats (3). They also reported that PGE₂ was significantly increased in the gastric mucosa (3). In human trials, LG21 strains administered through a yogurt drink have been reported to enter the gastric mucus layer and suppress *H. pylori* colonization in the stomach (1). In 2007, Lam et al. suggested that LGG could attenuate ethanol-induced apoptosis and enhance gastric ulcer healing (4). LGG has also been reported to stimulate mucus secretion and increase transmucosal resistance in the gastric mucosa (25).

Soy milk, a traditional food that has been used in China for thousands years, has been reported to be an antacid that can neutralize gastric juice to a pH above 3.0 (26). In our study, continuously feeding LAB-fermented soy–skim milk to rats for 28 days inhibited acute gastric lesions induced by pylorus ligation combined with acidified ethanol in a dose-dependent manner. However, nonfermented soy–skim milk, which is composed of the same raw materials except for LAB, had no significant effect on the gastric ulcer healing.

Oxidative stress could initiate and aggravate many diseases, including peptic ulcers and gastric carcinoma (27). The activities of SOD and catalase have a specific role in protecting the gastric mucosa against oxidative damage (28). Oral administration of acidified ethanol significantly increased the level of LPO in the gastric mucosa and decreased the activity of antiperoxidative enzyme. Except for the control group, the level of LPO was significantly decreased in each group. Groups 101-9 and 102-9 significantly enhanced the level of SOD activity in acute lesions in rats caused by pylorus ligation combined with acidified ethanol.

In 1998, Elliott et al. reported that bacteria rapidly colonize and modulate healing of gastric ulcers in rats. Gram-negative bacteria are likely responsible for the observed delay in ulcer healing, whereas Gram-positive bacteria may actually promote ulcer healing (29). However, soy–skim milk fermented with LAB is a natural food devoid of any side effects, and it is a novel alternative medicine for the prevention of gastric ulceration disease.

This is the first report that used pylorus ligation combined with acidified ethanol to establish gastric ulceration in an animal model. In previous studies, we used different models of acute gastric lesion, including chemical reagents (0.6 N HCl, 60% ethanol, and 0.15 M HCl + 70% ethanol) combined with pylorus ligation to compare the experimental time, status of the lesion, operative convenience, and deviation. Pylorus ligation combined with acidified ethanol is more appropriate to use as an experimental model (data not shown).

In summary, a 75:25 ratio of soy milk to skim milk fermented with *L. paracasei* subsp. *paracasei* NTU 101 or *L. plantarum* NTU 102 is useful for the prevention of acute gastric ulcers induced by pylorus ligation and acidified ethanol treatment through PGE₂ and significantly enhanced the level of SOD activity. These findings may indicate that LAB-fermented soy–skim milk is useful for the prevention of gastric ulcers.
