The hydrosilylation reaction of octa(hydrido)silsesquioxane with \(\omega\)-halo-1-alkenes and other unsaturated substrates allows attachment of 8 long-chain functionalized alkyls on the cubic Si\(_8\)O\(_{12}\) skeleton. Pt/C and H\(_2\)PtCl\(_6\) have been adopted as the catalysts, the yields being 74-98\% for compounds 2-9. For terminal alkenes, the hydrosilylation follows the anti-Markonikov’s rule. The morphological state of 2-9 ranges from viscous liquid to crystalline materials. The pyrolysis results indicate that 7, a material of hard spherical core and soft flexible shell, may likely act as nanometer-size ball bearings up to more than 400 °C. The X-ray structure of 9 reveals that the molecule is required to possess a center of symmetry crystallographically. The linear arms on 9, except for two of them, are virtually all-trans in conformation, not counting the \(\omega\)-C-Cl bond.

Keywords: Octasilsesquioxane; Hydrosilylation; Nanocomposites; Pyrolysis.

INTRODUCTION

Because of the length scales involved, nanocomposite materials incorporate extensive interfacial interactions that can result in non-linear changes in the composite property.\textsuperscript{1} Such changes in the nano region are so great that the rules commonly used to estimate the macroscopic property of composites no longer hold. The nanocomposites then offer potential access to completely new classes of materials with unique properties. One of the more difficult problems with nanocomposites is in developing synthetic and processing approaches that precisely define the volume and shape of individual phases and their periodicity.

Chemists often start from a much reduced domain-size and work at the molecular level, incorporating polymerizable inorganic and organic constituents in the molecule to build organic/inorganic hybrids that combine advantageous properties of disparate components.\textsuperscript{2} Silsesquioxanes (RSiO\(_{1.5}\)_\textsubscript{n}, derived from, e.g., RSiCl\(_3\) or RSi(OEt)\(_3\) by hydrolysis/condensation in a sol-gel process, are a class of silicate frameworks where each Si-atom is linked covalently to an organic radical R.\textsuperscript{3} Because of the introduction of R, these polymeric/oligomeric species are chemically modified silicates. Physically for instance, they have completely different thermal behaviors from silicates without modification. Structurally, silsesquioxanes consist of tetrahedral silicon atoms, each being a ‘T’ unit,\textsuperscript{4} i.e., connected to three O-atoms and one R group. The O-atoms are bridges between Si-atoms belonging to different T units, or between Si- and H-atoms. Among many other incompletely condensed silsesquioxanes is also the octa(hydrido)silsesquioxane, H\(_8\)-T\(_8\), which is completely condensed with a cubane-shaped structure, is suitable for more structural elaboration.\textsuperscript{5} The intention of this work is to produce hybrid nanomolecules from H\(_8\)-T\(_8\) via addition of organic moieties, the target being a Si\(_8\)O\(_{12}\) core carrying 8 functionalities for later use in starburst dendrimers.\textsuperscript{6}

RESULTS AND DISCUSSION

Attempted synthesis of H\(_8\)-T\(_8\) with solid acid route

H\(_8\)-T\(_8\) was first synthesized serendipitously in 1958 at <1% yield from HSICl\(_3\).\textsuperscript{7} There have been a number of improved preparations since. Agaskar reported a much more reproducible procedure in 1987 and described a purification protocol to yield gram quantities of H\(_8\)-T\(_8\), H\(_{10}\)-T\(_{10}\), H\(_{12}\)-T\(_{12}\),...
and H$_8$-T$_8$. Our current preparation follows the method reported by Agaskar in 1991, the yield of H$_8$-T$_8$ being 17.5% based on HSiCl$_3$. As large amounts of Bronsted acid HCl(aq) and Lewis acid FeCl$_3$(aq) were used in the Agaskar preparation, we thought about the possibility of using a solid acid as a replacement for HCl(aq) and FeCl$_3$(aq), and facilitating the purification steps after condensation. Thus the mixed CH$_3$OH/hexane in a round-bottomed flask over acid Amberlite (IR 120) was introduced with hexane-diluted HSiCl$_3$ from a dropping funnel over a long period of time, keeping the mixture under constant stirring. Then the standard Agaskar purification protocol yielded exclusively H$_8$-T$_8$, however in just 5.1% yield (Scheme I). According to our own experiences, the utility of solid acid Amberlite has improved many other preparatory methods. But the low yield of H$_8$-T$_8$ in this attempt was below expectations. A large percentage of insoluble resinous material was isolated whose $^1$H NMR spectrum clearly exhibited no proton resonance at all, suggesting the H loss during the sol-gel process of HSiCl$_3$ with addition of acid Amberlite.

**Scheme I**

Hydrosilylation on H$_8$-T$_8$ with alkenes

Among the principal objectives of this work is one directed towards the synthesis of novel, stable, polyhedral silsesquioxanes carrying various Si-R substituents. The direct condensation of RSiCl$_3$ to form R$_8$-T$_8$ in a sol-gel process involves both a monomer RSiCl$_3$ synthesis and a sol-gel procedure. For each different sol-gel preparation, there are different issues of side reactions and tedious optimizations. And hence modification on an existing Si$_8$O$_{12}$ skeleton without breaking apart the core is more commonly adopted. In the literature, vinyl-T$_8$, Ph$_8$-T$_8$, and H$_8$-T$_8$ all have been synthesized to serve as an intermediate and subject to modification to yield R$_8$-T$_8$.

In order to functionalize organic/inorganic nanocomposites, currently one of our attempts is to attach long-chain $\omega$-halogenated functionality to all of the Si-atoms on cubic silsesquioxanes, and we have carried out experiments on H$_8$-T$_8$ employing the hydrosilylation reaction, which is an important reaction in Si chemistry, converting Si-H bond to Si-C bond by 1,2-addition of the Si-H moiety onto an unsaturated C-C bond. In this manuscript, we report the reaction of H$_8$-T$_8$ and a series of $\omega$-halogenated terminal alkenes to produce new octa($\omega$-halo-alkyl) silsesquioxanes. The hydrosilylation reaction has been found to proceed with retention of the Si$_8$O$_{12}$ skeleton. Pt/C and H$_2$PtCl$_6$ have been adopted as the catalysts with various $\omega$-halo-1-alkenes as the unsaturated substrates (Scheme II): 4-bromo-1-butene, 5-bromo-1-pentene, 6-chloro-1-hexene, 7-bromo-1-heptene, and 8-bromo-1-octene; together with other unsaturated substrates: vinylcyclohexane, 6-chloro-1-hexyne, and 2-chloro-ethylvinylether. The reactions of the last three substrates are shown as examples in Scheme III. The hydrosilylation was carried out with excess unsaturated substrates at reflux. The yields were excellent following the anti-Markonikov’s rule for alkenes and the purification very simple. The reaction was monitored by $^1$H NMR spectroscopy, noting the disappearance of resonance at $\delta$ 4.19, and the emergence of appropriate peaks due to expected products. The products 2-9 were analyzed spectroscopically with good elemental analysis data. The morphological state of 2-9 ranges from viscous liquid to crystalline materials (Table I). The viscous nature of liquids with increasing carbon length attached to the Si$_8$O$_{12}$ framework was particularly observed.

**Scheme II**

The comparison between Pt/C and H$_2$PtCl$_6$ as the hydrosilylation catalysts is as follows. It was found that the latter, homogeneous in nature, effectively hydrosilylated all the unsaturated substrates listed earlier, whereas the former was selective towards that of $\omega$-halo-1-alkenes. There was no reaction when Pt/C was adopted as catalyst in the cases of vinylcyclohexane, 6-chloro-1-hexyne, and 2-chloroethyl-
vinylether to produce 7-9 (see Table 1, entries 6-8). Compared to Pt/C, H2PtCl6 has been judged to be more applicable overall, and its effectiveness at very low concentration has been quite remarkable. The production of 2-9 involves 8 steps of hydrosilylation reactions on a single Si8O12 skeleton; the yields ranging 74% - 98% suggest almost complete conversion for each step. The generally accepted reaction mechanism based on fundamental transition metal reactions in-

*At room temperature. All liquids are highly viscous. b No reaction.*
cludes oxidative addition of Si-H bond on Pt, olefin coordination, migratory 1,2-insertion of hydride, and reductive elimination, that is, the ‘Chalk-Harrod’ mechanism as further extended by Speier. The regioselectivity favoring linear products in the cases of ο-halo-1-alkenes as substrates is attributable to steric bulkiness of the Si₈O₁₂ core.

Compounds 2-9, prepared under nitrogen atmosphere, are stable under air. The ¹H NMR taken before and after exposing them to air for 2 h gave no differential observation. Overall the Pt-catalyzed hydrosilylation reaction of H₂-T₈ provides convenient access to ο-halo-functionalized cubic silsesquioxanes.

In the case of vinylcyclohexane (Table 1, entry 6), the steric energy of cyclohexane groups caused a relatively lower yield of 7. In the case of 6-chloro-1-hexyne (Table 1, entry 7), the products 8a,b were found to be a mixture of isomers, attributed to α- and β-additions. Gentle and Bassindale reported that β-addition and side reactions can be suppressed if the steric bulkiness on the γ-position of the unsaturated substrates increases. In the case of 2-chloroethylvinylether (Table 1, entry 8), the ether functionality might also have caused a slight decrease on the yield of 9 (cf. yields of 3, 4).

Pyrolysis of compounds 3, 7, and 9

Polysiloxanes, and a few of the octa(alkyl)silsesquioxanes have already received attention as precursors to ceramics and special glasses, for example, to silicon carbide, silicon oxycarbide and silicon oxynitride glasses. Out of the new R₅-T₈ compounds, only 3, 7, and 9 are solid samples whose thermolysis under normal conditions has been carried out in order to evaluate their relative thermal stability and possible ceramics-making potential. Fig. 1 shows the results of a thermogravimetric analysis study.

The three selected compounds are reasonably stable. All of them remain at constant weight below 350 °C, with the temperature of 10% weight loss occurring at 381, 442, and 338 °C, for 3, 7, and 9, respectively, compound 7 being the most stable. Both 3 and 7 have single step weight loss whereas 9 shows more than one step as reasonably expected from its ether linkages. The bromosilsesquioxane 3 is also seen thermally more stable than the chlorosilsesquioxane 9. The high thermal stability of 7 is attributed to its branching arms that carry one cyclohexyl group as the end group each (many more cyclic atoms on 7 relative to that on 3 and 9). Compound 7 is likely a much better material consisting of hard spherical cores and soft flexible shells that may act as nanometer-size ball bearings at above 400 °C. It has been conceived that at high temperatures, mineralization takes place. This degradation process involves the cleavage of many organic (and inorganic) bonds, leading to the escape of pyrolyzed small molecules before the formation of inorganic black glasses. The total weight loss of 7 and 9 exceeds 80% and is thus greater than the organic fraction of the materials, indicative of decomposition and rearrangement under the formation of larger siloxane structures and/or silicon oxycarbide.

X-ray crystal structure of 9

Compounds 3, 7, and 9 exist as solid microcrystals, out of which crystals suitable for X-ray diffraction studies were grown successfully for 9, from ether and from hexane/acetone. Single crystal X-ray structure analysis revealed clearly the molecular connectivity of 9, as shown in Fig. 2. The molecule is required crystallographically to possess a center of symmetry. The linear arms, except that extending from Si3, are virtually all-trans in conformation till ο-C-Cl. The arm extending from Si2 exhibits a disorder in the terminal region, the disorder being common in the X-ray structure study of silsesquioxanes. The structural parameters of the core Si₈O₁₂ are normal, similar to those found in the structures deposited in the Cambridge Structural Databases. On average of 9 published structures with an R-factor less than 0.10, the core Si-O bond length is 1.616 ± 0.007 Å, and the core ∠O-Si-O bond angle is 149.0 ± 4.3°.

EXPERIMENTAL SECTION

General

All manipulations were performed under an atmosphere of pre-purified nitrogen with standard Schlenk techniques, using a double-fold vacuum line. Most of the solvents

Fig. 1. Thermogravimetric analysis for 3, 7, and 9.
used were distilled from appropriate drying agents. IR spectra were recorded in CH₂Cl₂, using CaF₂ optics on a Perkin-Elmer 882 spectrophotometer. The ¹H and ¹³C NMR spectra were obtained on Bruker AC 200/AC 300 spectrometers. Chemical shifts are reported in δ values relative to the residual solvent resonance of CDCl₃ (¹H, δ 7.24; ¹³C, δ 77.0), C₆D₆ (¹H, δ 7.15), and d-acetone (¹H, δ 2.04). High resolution FAB-mass spectra were collected on a JEOL JMS-700 double focusing mass spectrometer with a resolution of 8000 (5% valley definition). For FAB-mass spectra, the source accelerating voltage was operated at 10 kV with a Xe gun, using 3-nitrobenzyl alcohol as matrix. Micro-analytical data were obtained with the use of a Perkin-Elmer 240C elemental analyzer, independently operated by the Institute of Chemistry, Academia Sinica. Thermal gravimetric analyses were performed on a Perkin-Elmer TGA-7 thermogravimetric analyzer where measurements were performed at a rate of 10 °C/min under air/nitrogen. The melting points were determined on a Fargo melting point apparatus and the values were uncorrected. Reagents/chemicals were obtained from commercial sources, e.g., Aldrich and Fluka, and used without further purification. Acid Amberlite (IR-120) was regenerated after use by washing with concentrated aqueous HCl, water, and methanol.

Synthesis of H₈-T₈, ¹

(a) With Agaskar procedure

FeCl₃ (anhydrous, 50 g) was taken in a round-bottomed flask, and concentrated aqueous HCl (20 mL) was added followed by CH₃OH (40 mL). Hexane (350 mL) was added, and the mixture was stirred. A solution of HSiCl₃ (20 mL, 0.2 mol) in hexane (150 mL) was added dropwise over a period of 9 h. After an additional 30 min of stirring, the upper hexane layer was transferred to another round-bottomed flask along with a suspended yellow solid. K₂CO₃ (14 g) and CaCl₂ (10 g) were added to the flask and the contents stirred overnight. The mixture was filtered, and the filtrate volume was reduced by evaporation until it was about 20 mL. ¹H NMR (C₆D₆): δ 4.19 (s, 8H). MS (FAB): 425.4 (M+).

(b) With attempted Amberlite procedure

A mixture of CH₃OH (30 mL) and hexane (150 mL) were put in a 500 mL round-bottomed flask containing acid Amberlite (IR 120, 50 g). While stirring, a 10-fold hexane diluted HSiCl₃ (4.0 mL, 0.040 mol) was added from a dropping funnel over a period of 6 h and then stirred overnight. The hexane layer was removed and put into a mixture of K₂CO₃ (14 g) and CaCl₂ (10 g) and vigorously stirred for 5 h. The filtrate was evaporated until it was less than 7 mL in volume. White microcrystals of I were exclusively collected in 5.1%
1.80-1.84 (m, CH2, 2H); 3.36-3.40 (t, CH2Br, 2H). 13C NMR (CDCl3): δ 10.90 (CH3); 21.35 (CH3); 33.52 (CH3). MS (FAB): 1504.04 (M+, parent ion).

Hydrosilylation reaction of H8-T8 with 5-bromo-1-pentene
H8-T8 (0.25 g, 5.7 × 10⁻⁴ mol) and 5-bromo-1-pentene (1.20 mL, 9.0 × 10⁻⁴ mol) were added to a 5.0 mL flask containing H8-T8 (0.25 g, 5.7 × 10⁻³ mol). The solvent and excess vinylcyclohexane were removed under vacuum to give a clear colorless viscous liquid {C6H11(CH2)2}8-T8 3. Yield = 98%.

Hydrosilylation reaction of H8-T8 with 6-chloro-1-hexene
H8-T8 (0.25 g, 5.7 × 10⁻⁴ mol) and 6-chloro-1-hexene (1.20 mL, 9.0 × 10⁻³ mol) were put in a 5.0 mL flask. Eight drops of 0.1 M H2PtCl6 in i-PrOH were added and the mixture heated at reflux for 10 h. Excess reactant was removed under vacuum to give a clear colorless viscous liquid {Cl(CH2)2}8-T8 4. Yield = 98%. 4: 1H NMR (CDCl3): δ 0.56-0.61 (t, SiCH2, 2H); 1.31-1.39 (m, CH2, 6H); 1.68-1.76 (m, CH2, 2H); 3.48-3.52 (t, CH2Cl, 2H). 13C NMR (CDCl3): δ 11.80 (SiCH2); 22.60 (CH2); 28.10, 28.58, 29.00, 32.40, 32.73 & 33.83 (all CH2). MS (FAB): 1306.7 (M+, parent ion). Elem. Anal. Calcd. for C30H60O12Si8Br8: C 29.73%, H 4.96%; Found: C 29.79%, H 5.00%.

Hydrosilylation reaction of H8-T8 with 8-bromo-1-octene
8-Bromo-1-octene (1.5 mL, 8.9 × 10⁻³ mol) was added to a 5.0 mL flask containing H8-T8 (0.25 g, 5.7 × 10⁻⁴ mol). Eight drops of 0.1 M H2PtCl6 in i-PrOH were added and the mixture heated at reflux for 10 h before vacuum-removal of excess reactant to give a light brown viscous liquid {Br(CH2)8}8-T8 6. Yield = 96%. 6: 1H NMR (CDCl3): δ 0.55 (b, SiCH2, 2H); 1.27 (b, CH2, 10H); 1.78 (b, CH2, 2H); 3.35 (b, CH2Br, 2H). 13C NMR (CDCl3): δ 11.80, 22.60, 28.10, 28.58, 29.00, 32.40, 32.73 & 33.83 (all CH2). MS (FAB): 1952.5 (M⁺, parent ion). Elem. Anal. Calcd. for C56H112O12Si8Br8: C 36.43%, H 6.13%; Found C 35.45%, H 6.84%.

Hydrosilylation reaction of H8-T8 with vinylcyclohexane
To a solution of H8-T8 (0.25 g, 5.7 × 10⁻⁴ mol) in hexane (10.0 mL) in a 25 mL flask was added vinylcyclohexane (1.80 mL, 1.3 × 10⁻² mol). Ten drops of 0.1 M H2PtCl6 in i-PrOH were added and the mixture heated at reflux for 3 d. The solvent and excess vinylcyclohexane were removed under vacuum to give a white solid {C6H11(CH2)2}8-T8 7, which was purified by washing with CH3OH. Yield = 74%. 7: 1H NMR (CDCl3): δ 0.54 (b, SiCH2, 2H); 0.79 (b, CH2, 2H); 1.13 (b, C6H11, 6H); 1.61 (b, C6H11, 5H). 13C NMR (CDCl3): δ 9.08 (SiCH2); 30.20 (CH2C6H11); 26.39, 26.80, 32.94, 39.94 (all C6H11). MS (FAB): 1306.7 (M⁺, parent ion). Elem. Anal. Calcd. for C34H72O12Si8: C 58.96%, H 9.27%; Found C 59.52%, H 9.60.

Hydrosilylation reaction of H8-T8 with 6-chloro-1-hexyne
To a solution of H8-T8 (0.25 g, 5.7 × 10⁻⁴ mol) in toluene (4.0 mL) in a 10 mL flask was added 6-chloro-1-hexyne (1.40 mL, 1.20 × 10⁻² mol). Six drops of 0.1 M H2PtCl6 in i-PrOH were added and the mixture heated at reflux for 8 h to give brown viscous liquid {Cl(CH2)2C=CHCH2}8-T8, {Cl(CH2)2C=CH2}8-T8.
Hydrosilylation of Octa(hydrido)silsesquioxane

T₈ 8a,8b (isomeric α and β hydrosilylated products which were not further isolated). 8a,8b: ¹H NMR (CDCl₃): δ 1.53 (b, SiCH₂, 2H); 1.69 (b, CH₂, 2H); 2.17 (b, CH₂, 2H); 3.46 (b, CH₂, 4H); 5.41 (d, CH, 1H); 6.36 (d, CH, 1H); 5.68 (b, CH₂, 2H). MS (FAB): 1357.1 (M⁺, parent ions for isomers).

Hydrosilylation reaction of H₅-T₈ with 2-chloroethylvinylether

2-Chloroethylvinylether (2.0 mL, 1.9 × 10⁻² mol) was added to a 5.0 mL flask containing H₅-T₈ (0.25 g, 5.7 × 10⁻⁴ mol). Eight drops of 0.1 M H₂PtCl₆ in i-PrOH were added and the mixture heated at reflux overnight before vacuum-removal of excess reactant to give off-white microcrystals which were washed with hexane {Cl(CH₂)₂O(CH₂)₂}₈-T₈. Yield = 98%. 9: ¹H NMR (CDCl₃): δ 1.06 (t, SiCH₂, 2H); 3.55-3.67 (m, CH₂OCH₂CH₂Cl, 6H). ¹³C NMR (CDCl₃): δ 19.58, 23.32, 23.49, 35.54, 51.99, 52.86, 53.19, 55.16 (all CH₂). MS (FAB): 1275.1 (M⁺, parent ion). Elem. Anal. Calcd. for C₃₂H₆₄O₂₀Si₈Cl₈:C 30.01%, H 4.98%; Found C 29.75%, H 4.91%.

X-ray structure analysis of 9

Diffraction intensities were measured with background counts made for half the total scan time on each side of the peak. Three standard reflections, measured every 60 min, showed no significant decrease in intensity during data collection. Data were corrected for Lorentz-polarization and absorption (empirical corrections). The structure was solved by direct methods MULTAN. Calculations and full matrix least-squares refinements were performed utilizing the NRCVAX program package. Disorders were found in that 2 extra atomic positions were also included in the final molecular structure: C₁₂ with occupancy 0.75 and C₁₂’ 0.25, C₂₅ with occupancy 0.50 and C₂₅’ with 0.50. All non-H atoms were refined with anisotropic thermal parameters with hydro- gen atoms fixed (C-H = 1.00 Å). Scattering factor curves of Cl, Si, O, C, and H were taken from the International Tables. Crystal data of 9: C₃₂H₆₄Cl₈O₆Si₈, FW 1277.16; Triclinic P̅₁; a 9.9719 Å; b 12.4123 Å; c 13.1479 Å; α 99.719°; β 95.264°; γ 84.052°; V = 1429.2 Å³; Z = 1; F(000) 664; Dₐ 1.477 g/cm³; μ 0.65 mm⁻¹; 2θ max 50°; Nonius CAD4 data; -10 < h < 10, 0 < k < 14, -15 < l < 15; crystal size 0.21 × 0.24 × 0.40 mm; transmission factors 0.483-0.868; & = 298 K; No. of calculated atoms 36; No. of calculated atoms 32; No. of refined atoms 325; No. of unique reflections 5038; No. of observed reflections 3618 [I > 2σ(I)]; R = 0.076; R_w = 0.106; Goodness of fit = 1.76; (Δ/σ)max = 0.0001; (D-map)max = 1.050 c/Å²; Minimizing function = Σ(w||F̅ᵣ² - |Fᵣ||²); Weighting scheme = counting statistics plus a weight modifier 0.05. Final fractional coordinates of non-hydrogen atoms are given in Table 2, selected structural parameters in the caption of Fig. 2.

ACKNOWLEDGMENT

The authors are indebted to the Institute of Chemistry, Academia Sinica and the National Research Council, Taiwan, ROC, for financial support. Thanks are due to Mr. Yuh-Sheng Wen for X-ray structure analysis and to Ms. Yuh-Sheng Wen for X-ray structure analysis and to Ms.
Ping-You Lin for high resolution FAB mass measurements.
