Study of the Fluid Flow in the Elliptical Duct by the Method of Characteristics

This study develops a mathematical model to determine the properties of laminar flow in the elliptical duct. With some assumptions, the nonlinear governing equations of the air in the elliptical duct are transformed into the hyperbolic type. The method of characteristics is then applied. Numerical results are obtained by using the finite difference method and the uniform interval scheme. The air properties in the elliptical duct are analyzed. The local Nusselt number and the heat transfer coefficient along the duct are studied. The numerical results are compared and show good agreement with the available data.

Introduction

The circumferential length of the elliptical duct is longer than that of the circular duct if the cross-sectional areas are the same. Hence, when the heat exchanger requires good cool effect and the space is an important factor in design, the elliptical duct is used practically.

The governing equations for the air flow in the elliptical duct are nonlinear. Bodoia and Osterle (1961) transformed equations to get the appropriate solutions by numerical methods. Lundgren et al. (1964) studied the pressure drop due to the entrance region in ducts with arbitrary cross sections. Igbal et al. (1972) used variational method for the steady fully developed laminar flow. Dunwoody (1962) investigated the steady, viscous and fully developed laminar flow with constant wall temperature for the entrance region. Gilbert et al. (1973) used the slug flow model and ignored the influence of the viscosity for the forced laminar and steady flow to determine the heat transfer on the boundary. Abdel-Wahed et al. (1984) investigated experimentally the laminar developing and fully developed flow with the ratio of the major axis length to the minor axis length being 2.

The purpose of this study is to develop a mathematical model to analyze the air properties and to determine the local Nusselt number and the heat transfer coefficient of the air in the elliptical duct.

Mathematical Approach

The coordinate system for an elliptical duct is shown in Fig. 1. For a laminar flow field, the gradients of the velocity components in the y and z directions are negligible compared with the gradient of the velocity component in the x direction. The energy generated by the friction force is assumed much smaller than all other terms.

At the location far from the duct wall, the speed and the temperature gradients and the second-order differential of the heat transfer and the viscosity are very small; therefore, their effects are negligible. Large variation exists only at the location near the duct wall. The air temperature at the duct wall is assumed to be equal to the temperature of the duct wall.

The assumed dimensionless temperature is used to simplify the second-order terms in the differential equations. The exponential form assumed for the temperature distribution is

\[ \theta = \frac{T(x,y,z) - T_w(x)}{T_c(x) - T_w(x)} \left( 1 - \left( \frac{y}{a} \right)^2 + \left( \frac{z}{b} \right)^2 \right)^{\frac{1}{2}} \]  

where \( T_c(x) \) is the highest air temperature at the duct center and \( T_w(x) \) is the air temperature at the duct wall. The exponential form assumed for the velocity distribution is

\[ \frac{u}{u_m} = \frac{u}{u_m} \left( 1 - \left[ \left( \frac{y}{a} \right)^2 + \left( \frac{z}{b} \right)^2 \right]^{\frac{1}{2}} \right) \]  

where \( u_m \) is the highest air velocity at the duct center in the x direction and \( u_m \) is the air mean velocity. The air is assumed to be an ideal gas.

The nondimensional variables used are
Using Eqs. (1), (2) and (3), the column vector $L$ of non-dimensional forms of the continuity, momentum and energy equations can be obtained as:

$$
\begin{bmatrix}
\rho^* \delta_{11} & \rho^* \delta_{21} & \rho^* \delta_{31} & U_1^* & 0 \\
\rho^* U_1^* & 0 & 0 & RT \frac{\delta_{11}}{u_{in}} & \rho^* R(T_{m}-T_a) \delta_{11} \\
0 & \rho^* U_1^* & 0 & RT \frac{\delta_{21}}{u_{in}} & \rho^* R(T_{m}-T_a) \delta_{21} \\
0 & 0 & \rho^* U_1^* & RT \frac{\delta_{31}}{u_{in}} & \rho^* R(T_{m}-T_a) \delta_{31} \\
\end{bmatrix}
\begin{bmatrix}
\frac{\partial u^*}{\partial x_i} \\
\frac{\partial v^*}{\partial x_i} \\
\frac{\partial w^*}{\partial x_i} \\
\frac{\partial p^*}{\partial x_i} \\
\frac{\partial T^*}{\partial x_i}
\end{bmatrix}
= \begin{bmatrix}
0 \\
0 \\
0 \\
0 \\
0
\end{bmatrix}
$$

where $\delta_{ij} = 0$ if $i \neq j$, $\delta_{ij} = 1$ if $i = j$

$$
[G]^* = -\frac{\mu u_{in}}{\rho D_h} \left\{ -\alpha_2 (\alpha_2 - 1) \left[ \frac{y^2}{a} + \frac{z^2}{b} \right]^{2\alpha_2 - 1} \right. \\
\left. \times \left[ \frac{4y^2}{a^4} + \frac{4z^2}{b^4} \right] - \alpha_2 \left[ \frac{y^2}{a} + \frac{z^2}{b} \right]^{2\alpha_2 - 1} \left[ \frac{2}{a^2 + b^2} \right] \right\}
$$

and

$$
[F]^* = \frac{k(T^* - T_a^2)}{\rho D_h} \left( T_{m} - T_a \right) \left\{ \frac{\alpha_1}{\alpha_2 (\alpha_2 - 1)} \right. \\
\left. \times \left[ \frac{y^2}{a} + \frac{z^2}{b} \right]^{2\alpha_2 - 1} \left[ \frac{4y^2}{a^4} + \frac{4z^2}{b^4} \right] \right. \\
\left. - \alpha_1 \left[ \frac{y^2}{a} + \frac{z^2}{b} \right]^{2\alpha_2 - 1} \left[ \frac{2}{a^2 + b^2} \right] \right\}
$$

The method of characteristics is applied by using the arbitrary functions $\omega_1, \omega_2, \omega_3, \omega_4$ and $\omega_5$ to combine these non-dimensional equations (Rudinger, 1969; Huang, 1992). Let the five coefficient vectors of the combined equation $L_1 \omega_1 + L_2 \omega_2 + L_3 \omega_3 + L_4 \omega_4 + L_5 \omega_5 = 0$ be related. Then, there exists a common normal vector for these coefficient vectors as:

$$
\begin{bmatrix}
\rho^* \delta_{11} \omega_1 + \rho^* U_1 \omega_2 + \frac{\rho^* RT}{c_v T_a} \delta_{11} \\
\rho^* \delta_{21} \omega_1 + \rho^* U_1 \omega_2 + \frac{\rho^* RT}{c_v T_a} \delta_{21} \\
\rho^* \delta_{31} \omega_1 + \rho^* U_1 \omega_2 + \frac{\rho^* RT}{c_v T_a} \delta_{31} \\
\rho^* U_1 \omega_1 + \frac{RT}{u_{in}} \left( \delta_{11} \omega_3 + \delta_{21} \omega_3 + \delta_{31} \omega_3 \right) \\
\rho^* \frac{RT}{u_{in}} \left( \delta_{11} \omega_4 + \delta_{21} \omega_4 + \delta_{31} \omega_4 \right)
\end{bmatrix}[G]^* = 0
$$

$$
\begin{bmatrix}
\rho^* \delta_{11} \omega_1 + \rho^* U_1 \omega_2 + \frac{\rho^* RT}{c_v T_a} \delta_{11} \\
\rho^* \delta_{21} \omega_1 + \rho^* U_1 \omega_2 + \frac{\rho^* RT}{c_v T_a} \delta_{21} \\
\rho^* \delta_{31} \omega_1 + \rho^* U_1 \omega_2 + \frac{\rho^* RT}{c_v T_a} \delta_{31} \\
\rho^* U_1 \omega_1 + \frac{RT}{u_{in}} \left( \delta_{11} \omega_3 + \delta_{21} \omega_3 + \delta_{31} \omega_3 \right) \\
\rho^* \frac{RT}{u_{in}} \left( \delta_{11} \omega_4 + \delta_{21} \omega_4 + \delta_{31} \omega_4 \right)
\end{bmatrix}[F]^* = 0
$$

If a four-dimensional normal vector and the velocity vector, respectively, are

$$
\begin{align*}
\alpha_1 & = \text{exponent of temperature distribution} \\
\alpha_2 & = \text{exponent of velocity distribution}
\end{align*}
$$

**Journal of Pressure Vessel Technology**

FEBRUARY 1993, Vol. 115 / 81
\begin{align*}
N_i &= (N_1, N_2, N_3, N_4) \\
U_i^* &= (u^*, u^*, \omega_i^*, 1) \\
\text{and} \\
\omega_i &= (0, 0, 0, 0, 0) \\
\text{or} \quad \omega_i &= (0, 0, 0, 1) \\
\omega_i &= (0, 0, 0, 0, 0)
\end{align*}

Each \( N_i \) defines a vector space which is normal to the normal vector and is also called the characteristic vector space. Using Eq. (10), two independent equations for each \( N_i \) obtained are

\[ \omega_i + \frac{R \left[ \frac{T_i - T_a}{T_i} \right] + T_d}{c_i T_a} \omega_i = 0 \]

and

\[ \omega_i N_i + \omega_j N_j + \omega_k N_k = 0 \]

Since Eqs. (13) and (14) are independent to each other, the simplest method is to consider \( \omega_i, \omega_j, \omega_k \) separately. When one of the two sets is considered, the other set is chosen to be zero as follows:

(a) \( \omega_i = (0, 0, 0, 0, 0) \)

From Eq. (13), we obtain

\[ \omega_i = \left\{ -\frac{R T' \left( \frac{T_i - T_a}{T_i} \right) + T_d}{c_i T_a}, 0, 0, 0, 1 \right\} \]

(b) \( \omega_i = (0, 0, 0, 0, 0) \)

From Eq. (14), the three variables \( \omega_i, \omega_j, \omega_k \) have only one restriction. The vector of \( \omega_i + \omega_j + \omega_k \) is just perpendicular to the vector of \( N_i + N_j + N_k \). The characteristic directions are arbitrarily selected as long as they are satisfied with the physical meaning and the simplification of the equations to reduce the computer time.

Using Eq. (11), we can obtain

\[ \omega_i = \left( c^{*2}, \gamma N_1 \frac{u_{in}}{c_a}, \gamma N_2 \frac{u_{in}}{c_a}, \gamma N_3 \frac{u_{in}}{c_a}, \frac{u_{in}}{c_a} \right) \]

When \( \omega_i \) in Eq. (15) is used, only one compatibility equation which is independent of \( N_i \) is

\[ (1 - \gamma) T' \left( \frac{T_i - T_a}{T_i} \right) + 1 \cdot D_{0b}^* + \rho^* \left( \frac{T_i - T_a}{T_i} \right) D_{0a}^* + \frac{u_{in}}{c_a} [F]^* \]

along the direction

\[ u = \left( u^*, \frac{u_{in}}{c_a}, u^*, \frac{u_{in}}{c_a}, w^*, \frac{u_{in}}{c_a}, \frac{u_{in}}{c_a} \right) \]

When \( \omega_i = (0, 0, 0, 0, 0) \) and the normal vector \( N_i = (1, 0, 0, -u^*) \) is selected to match the restriction of Eq. (10), \( \omega_i = (0, 0, 0, 1, 0) \) is chosen to match the restriction of Eq. (14). The compatibility equation is

\[ \rho^* D_{0b}^* + \frac{\rho^* R \left( \frac{T_i - T_a}{T_i} \right) + T_d}{u_{in}} D_{0a}^* + \frac{\rho^* \left( \frac{T_i - T_a}{T_i} \right) D_{0a}^*}{u_{in}} = 0 \]
Results

The data used in the analysis are shown in Table 1. If the duct is very thin and Biot number is less than 0.01, the wall temperature can be assumed equal to the air temperature which does not generate error more than 5 percent (Days and Crawford, 1980). Using the method of characteristics, the boundary values and the initial conditions of the elliptical duct should be given. The temperature on the surface of the duct is assumed isothermal. The variations of initial air temperature, pressure and velocity are all assumed linearly decreased along the duct. The initial data and the input air properties are shown in Table 2.

The nondimensional assumed data and the result of the air mean density and air mean temperature along the duct are shown in Figs. 2 and 3, respectively. The air temperature distribution at each cross section is shown in Fig. 4. The coordinates are expressed in the dimensionless reciprocal Graetz number $G_{f}^{-1}$. The dotted lines in Fig. 4 are data obtained by Dunwoody (1962) used for comparison. The nondimensional air velocity distribution along the duct is shown in Fig. 5. The velocities at the major axis and the minor axis along the duct are shown in Figs. 6 and 7, respectively.

Calculated local Nusselt numbers along the major axis and the minor axis for the isothermal elliptical duct are compared with the results of Dunwoody (1962) and Abdel-Wahed et al.
Fig. 8 Local Nusselt number along the major axis for the isothermal elliptical duct

Fig. 9 Local Nusselt number along the minor axis for the isothermal elliptical duct

The calculated results of the local Nusselt numbers along the major axis and minor axis for the isothermal elliptical duct are comparable with the results obtained by Abdel-Wahed et al. (1984), Dunwoody (1962), and Gilbert et al. (1973), as shown in Figs. 8 and 9, respectively. The calculated results agree very well with those obtained by Dunwoody (1962) and Abdel-Wahed et al. (1984) if the reciprocal Graetz number is increased. Therefore, the assumptions, chosen characteristic directions, arrangement and the density of the grids used in this analysis provide very good calculated results.

Conclusion
The calculated results of the three-dimensional flow in the elliptical duct are compared and show good agreement with the available data. The governing equations of the air flow were derived in general form. It is believed that the mathematical model can be extended to analyze the ducts with arbitrary cross sections if the assumed distribution functions are reasonable.
